Human Resources Allocation in Project Management

Roman Nedzelsky, , University of Economics, Prague, Czech Republic, roman.nedzelsky@vse.cz

Abstract:

Resource allocation is an important part of project management. This paper focuses on this area, especially on human resources allocation. The main paper's objective is two-fold: The paper introduces the notion of the Human Resources Information Set (HRIS) and the Human Resources Information Set Extension (HRIS_E), which are used in project scheduling and resource allocation. Various modes of HRIS_E use in project management are presented. Practical examples of HRIS_E use together with benefits obtained are also given. The direction of future research directed towards the advanced use of the concepts presented is charted.

Keywords: algorithm, project management, portfolio, human resource allocation

1. Introduction

Based on Project Management Institute - PMI (2013), the project is *„…a temporary endeavor undertaken to create a unique product, service or result"*. *A* project is temporary, it has defined beginning and end, defined scope and resources. A project is also unique because it is not some daily operation. It is set of tasks with the predefined flow of these tasks to create concrete output. Project management is on the other side defined, related to PMI (2013) as *„application of knowledge, skills, tools, and techniques to project activities to meet the project requirements*".

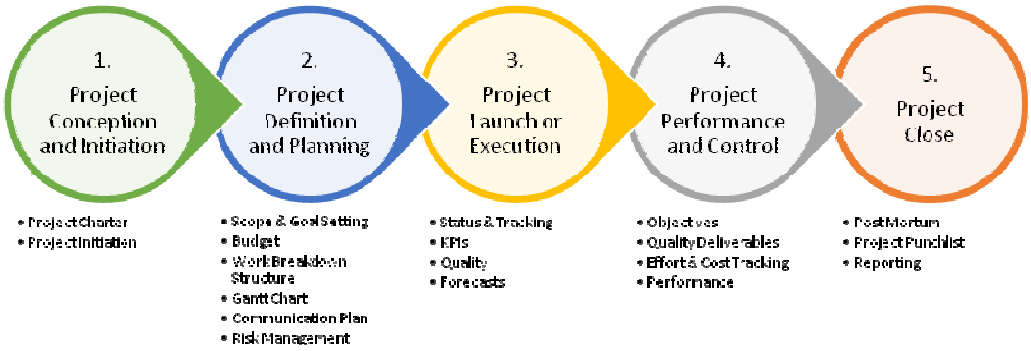

Figure 1 - Phases of project management based on PMI, source: author

Project phases with necessary documents based on PMI are shown in Figure 1. We want to mention particularly the monitoring phase, which is separate from all other phases of the project lifecycle. The monitoring phase runs through all the project phases and needs to be maintained periodically to prevent project issues. Software project management involves the scheduling, planning, monitoring, and control of the people, processes, and resources to achieve specific objectives while satisfying a variety of constraints. The Project Management is tightly bound with company core process, which involves resources through all company. These resources are divided into human resources, material resources, and financial costs. All these resources are allocated in projects and assigned to separate tasks. The problems are often in an overallocation of these resources because companies don't know how many resources they will need. Another issue related to resources is that the companies are not able to get as many useful resources to concrete role area as possible and needed for the projects. This paper is related

to algorithms which should be able to help with resource allocation and assignment problems in the field of project and portfolio management based on sets of information about these resources. Another purpose of this paper is trying to raise the efficiency of use of these resources is another purpose of this paper.

Based on research of Reunak and Osterweil (2005) the "classic" resource planning is done on the static level. When scheduling resources are, however, necessary to take into account the fact that the sources have often dynamic attributes (location, experience etc.). Hegazy (1999), which dealt with multi-objective optimization by using the techniques of genetic algorithms. Although additional information about resources was not taken into account. Based on research of Chang (2008) there was compiled algorithm that addresses the planning of a project based on individual task with its characteristics, skills, and experience. The main research gap is the missing integration of information sources and creation of extended information set. This set is described in section 3 and 4.

The remainder of this paper is structured as follows: Section 2 describes a common ground for section 3. Section 2 is divided into three parts on project management, algorithms for project management and project resources. Section 3, which is the core of the paper, is oriented towards human resources allocation. Section 4 concludes the paper.

2. Background

2.1 Project management

In project management, there is used **Project Management Triangle** (called also Triple Constraint or the Iron Triangle), i.e. the ratio between quality, time, and finances, which must be consumed on the project. Between these variables apply a rule that says that if one value is reduced, it is always at the expense of the other two. Chen and Askin (2009) mentioned, that there is, therefore, the need for constant project balance. It means that in the implementation of the project it is necessary to constantly calculate how individual staffing projects corresponds to the financial calculations for each project phase, i.e. what the rates are for each resource, how do individual tasks as effectively as possible, therefore, for a minimum period of time, with the best quality, for the least cost. This effectiveness should be raised by using algorithms described in section 2.2.

Projects are managed by the two basic techniques – **using the waterfall model, or agile**.

According to Mary (2013), the waterfall model represents the plan at the beginning of the project, which goes across the entire project lifecycle, and therefore includes estimates for each task through the entire project. The second approach – agile – is designed rolling planning, thus fixing the individual tasks to the closest time to come - for example, a week or a fortnight. Sometimes it is necessary to combine these two approaches together, thus establish the project plan with fixed estimates (for example, the project of implementation of an information system), which is part of the development of embedded software. For example, the task has a fixed length of fifty days, which is taken as a summary task and individual cycles with detailed planning tasks, then governed by, for example, a software architect.

2.2 Algorithms for Project Management

Algorithms for project management support project planning, resource allocation (of project resources to individual project tasks) and project optimization (based on given criteria). For these purposes, a great variety of algorithms and techniques have been used. Many of them have a different approach to solving problems of human resources or project planning. In most cases, the amount of important information is the main source for all of these algorithms. Another part is a matching of that information together in a right way. The results are in some cases great and efficiency is raised a lot. A number of resource allocation algorithms is presented by Kolisch and Hartmann (2009).

To review these algorithms, the samples of algorithms from the individual areas were collected, by the author, to describe them briefly and mention their advantages and disadvantages. Selected algorithms constitute the majority content of scientific articles (possibly with some modifications), and, according to the author, they are high-quality algorithms, which are actually applicable for optimizing of the allocation of human resources. It is obvious that some of the procedures are somewhat older; they often omit some influencing factors, such as the amount of input data, system dynamics and its possible combinations with machine learning systems, thus adaptability.

The individual algorithms can be assessed from several classic views as time complexity class of algorithm, etc. However, the algorithms could be assessed only on the specific case and on the basis of their direct measurement, because each of them is based on significantly different principles. It is important to take into account the individual characteristics, the amount of the input variables and the gradual determination of outputs and their classification. In the case of genetic algorithms, an indication of any amount received by the selection of offspring is necessary. These algorithms are typically characterized by high timeliness. For linear algorithms or the Hungarian algorithm, the procedure is significantly different, since it is based on a clean pass of optimization (matrix transpose algorithm). Below is a description of the selected algorithms that have been chosen in connection with the problem of optimizing the allocation of human resources, thus a multi-criteria optimization of the search on the basis of a predetermined volume of data input (human resources with properties). For the algorithms, no integration of information systems, nor any results on a set of data-entry to each of the participants was used. The algorithms have been selected on the basis of author's study of the topic in the literature.

Algorithms are divided based on Kolisch research (2010a, 2010b) into two basic groups – heuristic and genetic. The aim of heuristics is not to find the exact solution, but only an estimation. Genetic algorithms are based on the imitation of the biological evolutionary process, they gradually "grow" to the best solutions using mutation and crossbreeding. Overview of algorithms from the human resource management point of view is in section 2.3.

2.2.1. Heuristic algorithms

Multicriteria linear algorithm (goal programming approach)
Based on research of Azimi et al (2013), Morteza Rashmani Nikoei and Zinat Jamshidi (2013), Ozcan (2009) and Yanfeng Wang et al (2002), linear programming is a procedure in which it is taken into account several basic building blocks that make up this procedure. This is a set of output, which is determined by the starting point of the problem and cannot have negative values (the values x1, x2, x3, ...). Objective function describes the objectives, which the manager who solves the problem, trying to achieve — for example, revenue, profit, price. This variable is described as the cost of the resource, or as a source of profit, etc., he volume of the unit. Other areas are the constraints, which describe the limitations and the last are the parameters that describe the figures fixed sources.

Heuristic search algorithm
Heuristic search algorithms are, regarding Cummings and Bruni (2010), generally fast and complete, i.e., if there is a solution, even partial, the search algorithm will find it. However, heuristic search algorithms are hindered by their non-optimality: they can easily get stuck in local optima, hence offering no guarantee that the solution proposed is the best (provided there is an adequate measure of a solution's quality).

Hungarian Algorithm
This is the combinational optimization algorithm which solves the problem of allocation in polynomial time. The time complexity of the algorithm is $O(n^4)$ - O represents Time Complexity. Based on Edmonds and Karp it can be optimized to $O(n^3)$ – cubic time. This algorithm is fairly simple in its essence, because

of searching of values in the matrix instead of mathematical functions. Based on Srinivasan (2009) and Mills-Tattey et al. (2007), it is built on the principle of a gradual work with the matrix, where the lines are individual tasks and in the columns are resources.

Hungarian algorithm is often used, for example, to optimize the allocation of human resources to the specific tasks according to the costs of a specific resource on a task. With Its use, the cost component is therefore reduced, because the selected tasks should be done in the smaller amount of time. This algorithm can be used to count the highs, for example, where the company has four branches with different products and there is a need to properly distribute those products to these branches so that the company earned the most money in total. The algorithm is unfortunately limited to **one input criterion**, that is, the numeric value of the input, which makes it difficult for multi-objective decision making.

2.2.2. Genetic algorithms

Multi-ant colony optimization
Multiple ant colony optimization is a meta-heuristic approach inspired by ant colony algorithm – multiple in this concrete case means multiple ant colonies and the number of pheromone trails. The ant colony algorithm was inspired by ants, which are searching for an optimal way between the colony and food. Algorithm use in calculations communications between agents which is similar to ants, which are putting pheromones on trails to food – if there is longer way, the pheromone strength quickly fades out, so stronger pheromone means shorter way. This approach was firstly described by Dorigo et al. (1996) and Xiao et al. (2013).

Bio-inspired model
Based on an extension of the bio-inspired response threshold model and takes into account various aspects of the human resource allocation problem, such as the skills of available human resources, activity-related skill requirements as well as social ties/relationships among involved human resources. This model is described in more detail way in research of Karditsa, Griva et al. (2015).

Multi-objective genetic algorithm
As already mentioned, a lot of algorithms (for example, Putnam and Boehm model), which were created for the purpose of optimization of resources in the projects, they can't handle the multi-criteria allocation of these resources as it should be read in research of Ho and McDevitt (1990). A genetic algorithm is, based on Alba and Chicano (2007), one of the types of evolutionary algorithms (EA), which are widely used for the optimization of the different processes. The principle is the gradual creation of a generation of different solutions to a specific problem, where the solution maintains the so-called the population, in which each individual is a complete solution to the problem. It is obvious that in the formation of future generations it is, based on research of Wena and Lin (2008), possible here to apply the principles of "breeding" and thus achieve improvement solutions to the original problem – and the crossing of the various mutations of individuals.

Multi-objective hybrid genetic algorithm
Based on researches of Elihoub et al (2006), Ida et al (2011), Jaylakshmi et al (2001), and Kim (2012) - In multi-objective optimization problems, convergence and diversity are two important issues. The former indicates the algorithm's ability to find the true Pareto-optimal solutions, and the latter reflects the algorithm's ability to find as much as possible different Pareto optimal solutions. In order to improve the convergence of the algorithm, a local search based on critical path theory is incorporated into the H-MOEA.

Table 1 - Pros and Cons of selected algorithms, source Author

	Plus	Minus
Multicriteria linear algorithm	handling the bounds of the decision variables as they are initially presented	In this scenario complicated to program
Multi-objective genetic algorithm	Simple extension of single-objective GA	Usually slow convergence
Multi-objective hybrid genetic algorithm	Improved convergence speed to local optimal	Increased computational time per iteration
Heuristic search algorithm	generally fast and complete, will find also a partial solution	non-optimality: they can easily get stuck in local optima
Multi-ant colony optimization	Can be used for both static and dynamic combinational optimization problems	Convergence is guaranteed, although the speed is unknown
Bio-inspired model	analogies to various phenomena in nature and society	Weights assessment
Hungarian Algorithm	Simplicity	Multi-objective

Kotwal a Tanuja (2015) compared a group of genetic and heuristic algorithms on the specific experiment represented by the predefined amount of tasks and human resources that need to be split between these tasks. Based on the result of this research, it is recommended, that ideally use of the algorithm is the combination of both approaches – both heuristic and genetic. Kotwal and Tanuja (2015) called this combination as a heuristic mixed genetic algorithm. This research, however, disregards the main problem of our paper - use the extra set of input information, which would serve as the basis for the optimization of the use of the most effective algorithm for optimizing the allocation of human resources in project management.

2.3 Project resources

Project management is constantly trying to deal with the allocation of resources in the project. The allocation of resources, which is the main topic of this paper, assigns the resources to the specific tasks of the project. The allocation is carried out in phase 2 according to the Fig. 1. The company mostly does not address just one project, but generally more projects with these resources as it is evident from Fig. 2. Please notice in particular human resources, which is the subject of this paper.

	Resource 1	Resource 2	Resource 3	Resource 4
Project A	X			X
Project B	X		X	X
Project C		X		
Project D	X			X

Figure 2 - Resources allocation on projects, source Author

In many projects, the execution of some set of activities is limited by constraints, typically by resources availability. This situation leads towards the problem of Resource Constrained Project Scheduling

(RCPS). RCPS needs to answer the question, presented by Wall (1996): "*Given a set of tasks, resources, and the way to evaluate performance, what is the best schedule to assign the resources to the activities such that the performance is maximized?"*. Currently, extensive research is carried out in the RCPS area.

Algorithms used in current software tools, such as Microsoft Project Server, or Primavera work with the basic set of the resource information (see also Chapter 3). For example:
- availability of resources in comparison with the personal calendar,
- the total capacity of which is taken from the resource information,
- the role of the source, which is also taken from the personal profile.

Human resources have beside the resources' primary role other additional properties. Based on research of Hart (2012), Bowen (2012), Narahari and Murphy (2009), Raunak and Osterweil (2005), these properties often include a selection of skills (often technical, or professional specialization). They may be logged in the personal training plans, which also contain information about career direction and the motivations in professional life etc. This stored information can be used to optimize the allocation of resources. This information is usually available from various sources of information as mentioned by Chang et al. (2008). There is no rule that the company would retain all of that or more, but if they have this data, it is appropriate to use them. For this purpose, it is appropriate to integrate information units/systems and the subsequent information to consolidate in a centralized repository/Resource Center. This Center can be generally in the ERP system, or in a specialized system for project management support, as well as for portfolio management support.

When working with resources, in particular with human resources, it is necessary, based on Ballesteros-Perez et al (2013), Chantrapornchai et al (2013b), Lotz Mary (2013), PMI (2013) and Ziaidoostan et al (2013), to take into account the following circumstances

- In company resources circulate a lot (recruit and dismiss) and often are unique as well, therefore it is difficult to replace them. It is quite a problem in the case of planned projects with shared resources (see also fig. 2), and in the course of individual running tasks, one of the sources leaves the company and there is no one else, who would have handled the same work, or who would be able to execute the task in a predefined time frame with the same quality of work.
- Projects are carried out by resources typically for a predetermined price. However, new resources, which come to the company are sometimes able to perform the same job with the same quality for less money. The project Manager did not anticipate that, and the resource manager often does not manage it from the running projects view and He is providing for new projects within the portfolio only.
- It is necessary to take into account the additional properties for each resource. These can come from a number of information systems, and make up the difference in the current human resources planning and scheduling, which is related to the individual algorithms.

3. Human resources allocation

Resources used in the project management carry a **limited amount of input information**, i.e. information that describes the given source from the project management point of view. As it is mentioned in the introduction of this work, human resources represent a group of project resources, which has one of the largest sets of input information. Information systems which serve as a support for the project management use different algorithms for resource allocation. These algorithms, based on the input information, assign the appropriate project resources to the specific tasks of the project or projects (in a multi-project environment). In the case of human resources, this information creates (human) resource information set (HRIS). The content of HRIS differs for each of the allocation algorithms. The information included in the HRIS is listed in table 2 for some of the algorithms listed in part 3.

Table 2 - HRIS of allocation algorithms, source Author

	Cost information	Resource capacity	Role of resource	Resource Skill weight (number)	Task Skill weight (number)	Resource skill set
Multicriteria linear algorithm	X	X				
Multi-objective genetic algorithm		X	X			X
Multi-objective hybrid genetic algorithm	X	X	X			X
Heuristic search algorithm		X		X	X	
Multi-ant colony optimization		X	X			
Bio-inspired model	X	X	X			X
Hungarian Algorithm		X		X	X	

This information should be reflected in the process of its allocation to the specific projects, more precisely to its use in project management, especially in a multi-project environment.

Certainly, there is another wealth of information about human resources that is not included in HRIS and that would be appropriate to use in the allocation process as it brings advantage for the use of resources and project management (e.g. shortening of the project duration, see below). Set of these data will be labeled as HRIS_E (HRIS Extension). Adding this information to HRIS, EHRIS (Extended HRIS) will be created. EHRIS is saved in information systems of a company different from the information system for project management (PM IS). It is important to ascertain this data, to consolidate and to use them in allocation algorithms and project management software tools. These data have the crucial influence on the effectivity of the tasks conducted and thereby lead to a higher balance of the project´s portfolios, which is one of the core thoughts of project methodologies related to a multi-project environment of an organization.

Based on long-term practical experience of the author, the first version of E_HRIS includes following set of data:

A/ detailed specification of the work focus of the employee

If we take into account the implementation of a set of attributes related to specific roles of human resources in an organization, it is possible to better highlight the specialization of each employee. This leads to a fact that each employee will be conducting activities at which is he really the best (e.g. a developer will be developing in a specific programming language, an analyst will be analyzing a specific environment like retail or pharma etc.). Also on the other side, developer should have SQL database specialization in his skill set. So If Project Manager doesn't have someone for concrete SQL DB related task, this developer should do it and maybe in more efficiency way, because of learning of something new.

Practical benefits

Based on the author´s experience, after application of the detailed skill set of a source the duration of the conducted task has been shortened by almost one third. This is an important finding, however, there might be an allocation problem in the case that it is not possible to find a free resource as every resource with the demanded skill set is allocated to another project. Then a resource can be found who has no specific role (e.g. a developer), but who has development of a specific programming language at a junior level in his skillset. This resource can hold this post until an appropriate resource has been released for this project. This means that the project will not be prolonged due to resource reallocation that is also an optimization of the project from the project duration perspective.

B/ information from education plan of the employee

If we focus on resources information based on his educational plans - that in his spare time he develops himself in a particular focus, it is possible to work with this information as well. It is possible to put a space in the project such a source, and from the personal experience of the author, the source held activities on the project with more effectivity and concern. Often there are the groundbreaking concepts and scenarios often developed. These devotes personal time and these vice activities will do much faster and at a higher quality. At the same time, practical experience thus obtained is utilized in personal development. Such a procedure is, of course, necessary to support by a multitude of other soft skill techniques, however, it is already a procedural matter not covered in conjunction with algorithms for optimization.

Practical benefits
In practice, there was used the previously mentioned educational plan and experienced developers working on the project have been made concerning the development of the code in a cloud-based environment with the participation in the development of business intelligence over the resulting code. This scenario reduced time by 10-15 percent. And here the result has more than one measure:

- Duration of the task was reduced (the resource was more motivated and want to learn something new),
- the new concept was bored during the execution of the project tasks,
- this concept starts development of a new product in the company.

In further research, the author focuses on the expansion of E-HRIS for more information about human resources. Based on both his long-term practical experience as well as from the study of literature.

The use of E-HRIS in project management
The next stage of the research is to determine how to use E-HRIS and therefore HRISE in project management. This way we denote as PMM (Project Management Mode). Two basic modes should be defined for PMM:

- **Basic mode PMMS (Simple PMM)** – basic
- **Integrated mode PMMC (PMM Complex)** – complex

PMMS
In this case, the project manager is created HRISE. The relevant information in the E-HRIS ("manually") are provided by him into the corresponding information systems in the organization. Information are then transformed into the smaller set, required by the used resource allocation algorithm. That is, it uses the resource allocation algorithm, which does not directly support the information from the E-HRIS. This mode uses the author in the present stage of research.

PMMC
In this case, resource allocation algorithm directly supports the information from E-HRIS, even from across the HRISE. This information set is automated and online synchronized from the corresponding information systems across the Organization and creates new, specified “information system” strictly for project and portfolio management. To ensure this mod is a must, in addition to HRISE, to ensure in particular the following conditions:

- HRISE support by the algorithm
- Application integration in various information systems of concrete organization with PM application
- PM application ensuring referred mode

Depending on the method and extent to ensure the above conditions there is a possibility to define additional mods "lying in between the" PMMS and PMMC.

4. Conclusion and further research

Author’s contribution to human resources allocation in project management is presented in section 3. It is based on author‘s research work as well as on his long-term practical experience in project management. The notion of HRIS is presented, which is mapped towards several widely used algorithms for project management, as well as the notion of HRIS, for which also the first version of the practical content is presented. Based on these two notions the notion of PMM i.e. the mode of human resources information use in project management is defined. Besides the theoretical contribution the author‘s work has a significant contribution to praxis. This is documented by presentation of practical benefits of his work, although they were implemented with first author’s version of HRISE and in PMMS mode.

There are several directions of further research. Extension of the current version of HRISE may be seen as a shorter-time goal. Then the long-term goals are directed towards research and implementation of PMMC.

Abstract

Corporate Social Responsibility has multiple facets and has been practiced and implemented for several years in the Indian context. The new Companies Act India, formulated in 2014 includes mandatory expenditure requirement on Corporate Social Responsibility. This is designed to encourage firms to contribute towards some of the most critical societal needs. This paper attempts to assess the type and strength of the bi-directional relationship between corporate social performance and corporate financial performance in the Indian context by looking at the Top 141 Indian companies across 15 industries over the years 2013, 2014 and 2015. The relationship between CSP and prior-CFP for the applicability of the theory of slack resource availability is gauged. The theory of good management is validated by assessing CSP contribution to future-CFP of firms. Also, assessed are the effects of control variables such as industry and R&D on the relationship. The result shows a strong positive relationship between CSP and CFP and validates both slack resources theory and good management theory. The slack resources theory and good management theory provided mixed results when the control variables were industry and R&D.

Keywords: Corporate social responsibility, corporate financial performance, Indian firms

Introduction

Corporate Social Responsibility has been gaining a lot of prominence in recent decades as companies are expected to have a moral obligation towards society. Milton Friedman, 1970, and several neo-classical economists have strongly advocated against the use of a company's resources for purposes other than maximizing shareholder returns. Friedman famously said that 'a corporation's social responsibility is to make profit'. This has led to several arguments, theories and research that have tried to understand the relationship between a firm's corporate social performance (CSP) and corporate financial performance (CFP). A positive relationship has been observed between the two parameters in many studies (Cochran and Wood, 1984,Waddock and Graves, 1997) while several other studies have found a negative relationship(Shane and Spicer, 1983) while a few other studies have found no relationship at all(Margolis and Walsh,2003). However, Beurden and Goessling, 2008, have specifically asserted the positive correlation between corporate social and financial performance in Western societies.

Similar studies have been conducted in other non-western societies across the world and the results have varied from country to country – Taiwan (Yang et all, 2010), Tunisia (Dkhili and Ansi,2012), Brazil (Criso´stomo et al., 2011).

However, in India, the study of CSP-CFP relationship is limited by scope and extent (Mishra and Suar, 2010). CSR in general has been analyzed and studied through multiple surveys (Khan and Atkinson,

1987) while some studies have tried to explore the various definitions of CSR and studied the current CSR practices in India (Gautam and Singh,2010), other studies have looked at CSR in Indian government-owned firms (Subramanium et.all ,2015). Mishra and Suar, 2010 have looked at the relationship between CSP and CFP but its focus has been only on the manufacturing companies in India. Though India is one of the fastest developing countries in the world with a large number of corporate firms, there hasn't yet been a comprehensive study that looked at the CSP-CFP relationship across several firms and industries. A few papers have assessed the linkage between CSP and CFP parameters as outlined in Margolis and Walsh, 2003 but these papers have only looked at a single industry. This paper attempts to bridge that gap by studying 141 firms across 15 industries over the years 2013, 2014 and 2015.

Corporate Financial Performance

There are more than 80 financial measures to assess the CFP of a firm (Griffin and Mahon, 1997). Researchers have been inconsistently using measures based on availability of data. Some researchers have used 5-year return on equity (Cochran and Wood, 1984) or return on assets (Wokutch and McKinney,1991). Many papers have looked at three key measures- Return on Assets, Return on Equity and Return on Sales and have concluded that Return on assets is the preferred financial measure (Waddock and Graves, 1997). In this paper, return on assets is used as the measure for corporate financial performance.

Corporate Social Performance

Corporate social performance is a multi-dimensional construct with several parameters which lead to several inconsistencies and varied results for the linkage between CSP and CFP. Several past studies have used the Fortune reputation index (McGuire et al., 1988) but many others have claimed problems with this index (Fryxell and Wang,1994). The KLD database has been used more frequently to determine the CSP from a stakeholder's perspective. However, several researchers have found Fortune reputation index to be similar to KLD index (Griffin and Mahon, 1997) and have found support (Waddock and Graves, 1997) for researchers using the Fortune reputation index. Moreover, Stanwick and Stanwick,1998 looked at the fundamental question- whether the Corporate reputation index is a valid measurement of a firm's CSP by looking at relationship between CSP and three organizational variables, including the firm's environmental performance. The results conclusively proved that corporate reputation index is a valid indicator of the firm's overall CSP.

The KLD index is not available for Indian corporate firms. In the absence of the KLD index and the need for a more comprehensive look at the multi-dimensional construct for CSP, the Fortune's annual ranking of Indian firms, also called as Fortune's most admired companies which is similar to the Fortune reputation index was used. This index has more than 10 parameters to determine the final score for a firm. The various parameters are Corporate Governance, endurance, social impact, investment value, product/service quality, innovativeness, leadership quality, talent development, employee empowerment and global footprint.

Use of control variables

Several studies have put forth the theory that in order to obtain a positive relationship between CSP and CFP, multiple control variables such as size, industry (Callan and Thomas 2009; Margolis and Walsh

2003; Russo and Fouts 1997) need to be used. Research and Development which is considered a discretionary spending is also suggested as another control variable (McWilliams and Siegel 2001). This paper analyzes both industry and research and development as control variables.

Hypotheses formation

The CSP-CFP relationship involves 2 empirical issues that need to be addressed- 1) direction of the relationship- positive, neutral or negative and 2) Causal relationship- Does corporate social performance influence corporate financial performance and vice-versa (Preston and Obannon, 1997). Combining these two dimensions result in six causal and directional hypothesis.

Direction of relationships

Stakeholder analysis is used to understand the positive relationship between CSP and CFP. Both internal and external stakeholders are critical in running a business. A firm will always act in the favor of stakeholders if the strength of the stakeholders is high (Ullman, 1985). Stakeholders vary from customers, employees, bondholders, shareholders, suppliers to community and environment. Responding positively to stakeholders will result in a better reputation of the firm which will lead to better financial performance (Waddock and Graves, 1997). The strategic posture of the organization is critical to improving economic performance (Ullman, 1985). For e.g., customers would view products from the company to be of superior quality leading to higher sales, top employees will be attracted to the company which will improve productivity (Moskowitz, 1972). These activities will in turn help in improving the financial performance of the firm leading to a positive relationship between CSP and CFP.

A negative relationship promotes the idea that firms that are involved in socially responsible behavior are taking away resources from the firm's primary activities and incur costs thus resulting in the negative financial performance (Aupperle, Carroll, and Hatfield, 1985). Friedman(1970) and several neoclassical economists have argued that a firm should be only involved in maximizing profits.

Considering the wide range of factors associated with measurement of corporate social performance leads to the theory that there is simply no relationship between CSP and CFP. Corporate social performance is a multi-dimensional construct with several parameters which lead to several inconsistencies and varied results (Ullman, 1985).

Causal Relationships

The direction of the relationship between CSP and CFP is evaluated. Does social performance help in the improvement of financial performance or does the financial performance help in the improvement of social performance. These can be listed as two theories: Slack resources theory and Good Management Theory (Waddock and Graves, 1997).

Good management theory tries to explore the role of management in building and managing relationships with key stakeholders. A positive perception of the firm by external stakeholders such as customers, communities will improve sales, reduce costs and improve productivity (Moskowitz, 1972). These factors will positively influence the financial performance of the firm. The Hypothesis for this would be:

H1: Good compliance with corporate social performance guidelines yields better financial results.

According to the slack resources theory, firms will engage in social responsible ways only if they have adequate financial resources. If the financial resources of the firm are limited, then the firm will use those resources for purposes that will improve its financial performance and would not consider allocating those resources for socially responsible activities. This leads to the following hypothesis:

H2 : Good financial performance leads to better corporate social performance.

Methodology

The Top-198 companies spread across 15 industries were selected for this study. The industries were selected based on the highest impact on the Indian economy in terms of contribution to national GDP, growth rate, maturity of industry and competition in the industry. The top companies in each industry were selected based on their turnover, market share and CAGR (Fortune, 2014).

Out of the 198 companies selected for the study, multinational companies were removed from the list even though they had significant operations in India as the financial influence of their headquarters on their Indian operations could not be properly assessed. A few companies that lacked proper financial statements were removed. This reduced the final list to 141 Indian companies. The listing of companies across each industry is provided in Table-1.

Table 1: Listing of companies and industries

Industry	Total
Auto Components	10
Automotive	6
Banking	11
Capital Goods	11
Cement	13
Consumer Durables	8
Engg and Construction	10
FMCG	10
Iron and Steel Metals	11
IT and ITES	4
NBFC	9
Oil and Gas	12
Pharma and Healthcare	12
Power	8
Telecom	6
Grand Total	141

Corporate financial performance of the firms was calculated using ROA (return on assets). Data for the ROA was obtained for 3 years viz. 2012-2013, 2013-2014 and 2014-2015. The data was obtained from the Economic Times ET500 database. In India, the financial year runs from April 1st through March 31st of next year.

Corporate social performance of firms was obtained from the Fortune's list of most admired companies, 2014. The methodology involved two phases- phase-1 and phase-2. Phase-1 involved 523 companies. The intensity in engagement with respondents, and the respondents who demonstrated low intensity were eliminated. After the usage of validator questions and statistical validation, the final list reduced to 443 responses. Respondents evaluated the companies on a multi-dimensional construct that consisted of ten parameters viz. corporate governance, endurance, social impact, investment value, product/service quality, innovativeness, leadership quality, talent development, employee empowerment and global footprint.

The top-3 companies were selected from each of the 15 industries was further selected and was again re-assessed by 84 respondents on the same ten parameters. This led to final scores that were provided to the companies. The ten parameters and evaluation criteria are listed below:

- Corporate governance: the extent to which the company ensures consistent management, cohesive policies, accountability etc.
- Endurance: Consistency in the company's overall performance during recession or any other lean period.
- Social impact: The degree of positive impact the company's business activities have on the society and the environment it operates in.
- Investment value: The strength of a company's finances, operational cash flows and overall asset management.
- Product/service quality: The value of the quality of products and services delivered by the company to its customers.
- Innovativeness: The company's ability to understand its environment and customers, and offer breakthrough products and services
- Leadership quality: The level of competence, managerial skills, and business understanding of the company's top management team.
- Talent development: The company's ability to groom individuals who go on to occupy leadership positions in the firm and industry.
- Employee empowerment: The extent to which the company's employees are allowed to take key decisions related to their area of work, and the feeling of empowerment that they enjoy.
- Global footprint: The extent of the company's presence in the market that allows it to increase the magnitude of business activities, diversify resources, and increase revenue and profit.

Control variables

There are a total of 15 industries in the sample. Industry as a control variable and the relationship between CSP and CFP within each industry is assessed. Companies within the same industry are grouped together as they all face same challenges, similar issues and problems. The R&D values across the companies have been obtained and used as a control variable. They are grouped into firms having high R&D investments and low R&D investments.

Discussion and Results

The sample is composed of 198 Indian companies whose corporate social performance score was retrieved. After removing the multinational companies and companies that lacked proper financial data, the sample consisted of 141 companies.

The top 3 companies in each of the 15 industries were selected and further assessed on the ten parameters discussed above resulting in a score for these companies. This set of companies was analyzed for relationship to the corporate financial performance using ROA.

H1: Good compliance with Corporate social performance guidelines yields better financial results.
Good Management Theory

Variables used in H1

Social Variable (Corporate social responsibility score used as dependent variable)	Financial Variable (Return on Assets for the following year ,2015 is used as independent variable)
CSP Score for the year 2014	ROA for the year 2015

H2 : Good financial performance leads to better corporate social performance.
Slack Theory.

Variables used in H2

Financial Variable (Return on Assets for the previous year ,2013 is used as dependent variable)	Social Variable (Corporate social responsibility score used as independent variable)
ROA for the year 2013	CSP Score for the year 2014 from Fortune

Overall relationships

The table 2 summarizes relationship between corporate social performance and corporate financial performance. Here CSP for 2014 is taken and analyzed with 2015 Return on Assets value. Pearson Coefficient value is 0.527 and P value is 0.001 which indicates strong positive relationship between the two variables.
This validates our first hypothesis- H1: Good compliance with Corporate social performance guidelines yields better financial results.

Regression analysis results are shown in the table 3 for Slack Theory. Here CFP for 2015 is taken and analyzed with 2014 Corporate Social Performance value. Pearson Coefficient value is 0.492 and P value is 0.009 which indicates strong positive relationship between the two variables.

This validates our second hypothesis- H2 : Good financial performance leads to better corporate social performance.

Relationship when industry is control variable

The two hypotheses are tested for the industry control variable. The CSP-CFP relationship is assessed for each of the 15 industries listed. When Corporate financial performance is independent variable and Corporate social performance is dependent variable, the industries that show strong positive relationships

are Cement, FMCG and Telcom. These industries support the good management theory with strong relationship. Automotive, Consumer Durables, Engg and construction, Iron and Steel metals, NBFC, Pharma and Healthcare show negative relationship. Rest of the 9 companies show weak positive relationship.

Overall, it cannot be concluded that good social performance leads to better corporate financial performance and the Hypothesis-1 cannot be validated when industry is a control variable.

The industries that show strong positive relationship between Corporate Social performance (2014) and Return on assets 2013 are Capital Goods and Telecom. Eleven industries show weak positive relationship. However negative relationship was found in 4 industries. They are Automotive, Iron and Steel Metals, NBFC and Oil and Gas.
Overall, it cannot be concluded that good financial performance leads to better corporate social performance and the Hypothesis-2 cannot be validated when industry is a control variable.

Relationship when R&D is control variable

When R&D is used as control variable to test hypothesis-1, companies that have lower R&D value showed strong positive relationship between corporate financial performance 2015 and corporate social performance 2014, supporting Hypothesis 1.Weak positive relationship was found in companies with high R&D value.

Overall, it cannot be concluded that good social performance leads to better corporate financial performance and the Hypothesis-1 cannot be validated when R&D is a control variable.

For Hypothesis 2, companies that have lower R&D value showed negative relationship. Companies with higher R&D value show moderate positive relationship.

Overall, it cannot be concluded that good financial performance leads to better corporate social performance and the Hypothesis-2 cannot be validated when R&D is a control variable.

Regression analysis results are shown in the table 2 to assess Good Management Theory:

Independent variable= Return on Assets (2015), Dependent Variable= Corporate Social Performance (2014).

Table 2: Overall relationship, CSP dependent variable

R Square	Adjusted R Square	P value	Pearson Coefficient
27.8	25.6	0.001	0.527

Regression analysis results are shown in the table 3 to assess Slack Theory.

Independent variable= Corporate Social Performance (2014), Dependent Variable= Return on assets (2013)

Table 3: Overall relationship, ROA dependent variable

Higher R&D	24.3	14.8	0.147	0.490
Lower R&D	2	-10.8	0.890	-0.044

Conclusion

In this paper, the relationship between corporate social responsibility and corporate financial performance in the top 141 firms across 15 industries in India was assessed. The results indicate a strong positive relationship between corporate social performance and corporate financial performance. The slack resources theory which states that firms will engage in socially responsible ways only if they have adequate financial resources is validated. This was validated by looking at relationship between 2013 ROA and 2014 corporate social performance. The good management theory reviews the relationship between the firm's ability to manage relationships with its important stakeholders and its impact on the

financial performance. This theory has been validated by looking at the relationship between 2014 CSP and its impact of 2015 CFP. The impact of the two control variables – size and R&D on the CSP-CFP relationship is inconclusive. The slack resources theory and good management theory provided mixed results when the control variables were industry and R&D. We can conclude that the control variables (size and R&D) had limited effect on the relationship between corporate social performance and corporate financial performance. However without the control variables, we observe a strong positive relationship between corporate financial performance and corporate social performance.

Limitations and Future Research

There are a few limitations of this study. First, the measure of corporate social performance may narrowly look at meeting the needs of the stakeholders that improve the financial performance of the firms. India has a range of social issues ranging from education, poverty, malnutrition and empowerment. The corporate social performance measure of the firms may not actually reflect their work in alleviating these concerns. A comprehensive corporate social performance measure that is strengthened by incorporating actionable outcomes (Mishra and Suar, 2010) will truly reflect the social responsibility of the firms. Second, there are large and relevant literatures available on principles, processes and consequences to stakeholders of business activity, both beneficial and harmful, but they have not been brought into the CSP fold (DJ woods, 2010).

The Indian government through the new Companies Act (2014) has made it mandatory for firms that meet certain financial thresholds to include expenditure that support corporate social responsibility. The government has also laid out a clear reporting structure that details the various aspects of social issues and the firm's contribution towards these issues. A future study can look at incorporating the results from these reports and build a more comprehensive corporate social performance measure to assess the linkage to corporate financial performance.

Migration in EU

Hana Tomášková, Faculty of Informatics and Management, University of Hradec Kralove, Hradec Kralove, Czech Republic, hana.tomaskova@uhk.cz,
Jitka Kühnová, Faculty of Science, University of Hradec Kralove, Hradec Kralove, Czech Republic, jitka.kuhnova.2@uhk.cz

Abstract

Migration of foreigners is more and more mentioned and dreaded topic recently. There is a lot of independent theories, present or past, that tried to explain migration according to different fields of study. Each theory explains some type or aspect of a migration according to an event and an epoch when it was created. These theories can be distinguished mainly by what is considered as the main reason and by which questions they are looking for answers.

We can say that there is no integrated theory that would cover all of migration theories because each branch of science provides different sight on this term. As there is so many different theories we will deal only with a couple of them.

Keywords: Migration EU, migration theories

Introduction

The concept of a word migration generally means a moving of people from one place to another. “The term migration can be defined as a process more or less bounded in time of shift of people between places divided by national borders.” (Šiklová, 1998). Therefore we can split the migration as a domestic migration and an international migration where a domestic migration defines a change of a permanent residence over some administrative unit and an international migration stands for a change of an usual residence over a state border. There is a question how long someone should be at a new place to be considered as a migrant. OSN puts one year as a limit boundary. The international migration has a huge demographic, political, social, cultural and psychological impact on tranzit and the most on immigrant states.

If we consider time, we can split migration into short-term and long-term migration. The short-term migration is usually because of a job, study or recreation. The long-term migration means permanent change of residence. If a migrant is sole person, we talk about an individual migration. On the other hand, the collective migration covers bigger groups of people, usually families to reunite. Other aspect of migration is a reason and motivation that can be voluntarily or involuntarily, because of a political or an economical situation, catastrophes or other threatening factors.

Migration

The word “migration” comes from the latin word “migratio” which means “moving”. Oxford Dictionaries use a definition: „Movement of people to a new area or country in order to find work or better living conditions:the extensive rural-to-urban migration has created a severe housing shortage”.

Process of migration is analyzed by many authors. In this subsection, we will discuss migration variables proposed recently by Bonasia and Napolitano (2012), Cattaneo (2008), Czaika and Vothknecht (2014), Czaika (2015), Jennissen (2004), Kurunova (2013), Polgreen and Simpson (2011), Tupa and Strunz (2013) and van der Gaag and van Wissen (2008).

Cattaneo (2008), Jennissen (2004), Kurunova (2013), van der Gaag and van Wissen (2008) showed that factors they analyzed have a strong connection with standard economics theories. Cattaneo

(2008) done a research based on determinants that was identified by Harris-Todaro and on human capital theories. His analysis involved differentials of wages, unemployment rates and personal characteristics including differences between migrants and non-migrants. Van der Gaag and van Wissen (2008) and Kurunova (2013) supplied analysis with financial, demographic and social variables. As we look at the Jennissen (2008) study, we see that, in addition to factors as wages and unemployment, he has drawn attention to factors proposed by dual labour market, new economics and relative deprivation theories as shortages at the bottom of the labour market, the certainty of sufficient household income and the level of income inequality. He also analyzed determinants from theories of interntional movement solvents.

International migration flow between unrestricted mobility regions such as the European Union, and that is why it should be studied more precisely (Cushing & Poot, 2004). Fluctuations in emigration and immigration in the EU are frequent over the last decade, especially during different periods of economic downturn and growth. However, the use of push-pull perspective could be useful in such cases (Zimmermann, 19996).

In a year 2014, there was the most people on the move since the end of the World War II globally according to OSN. Around 59.5 millions of people were forced to leave their homes. Fig. 1 shows the migration in Europe and in a world from the year 1960 till 2014. The total number of international immigrants rose from 80 millions to almost 240 millions of people, which is almost three times. But it corresponds with the total population, the proportion of immigrants rose from 2,3 % to 3,2 %. On the other hand, in absolute numbers, numbers of immigrants in Europe rose also almost three times (from 20 millions to 60 millions) but the proportion of immigrant went from 3,4 % to 9,8 % (MPI, 2016). In a Fig 2., we can see the population change by component EU-28 with respect to Natural Change, Net Migration and Total population Change. Natural change shows the difference between the number of live births and deaths during the year, Total population change shows the difference in total size of a population at the beginning of a year and at the end and the last one, Net Migration shows the difference between the number of immigrants and emigrants during the year. Eurostat calculate this Net Migration as a difference between Natural change and Total change in a population; this method is known as “statistical adjustment”.

We can see as natural change in European population is decreasing, growing migration “helps” balance this drawdown which can be seen as slowed decrease of total population change.

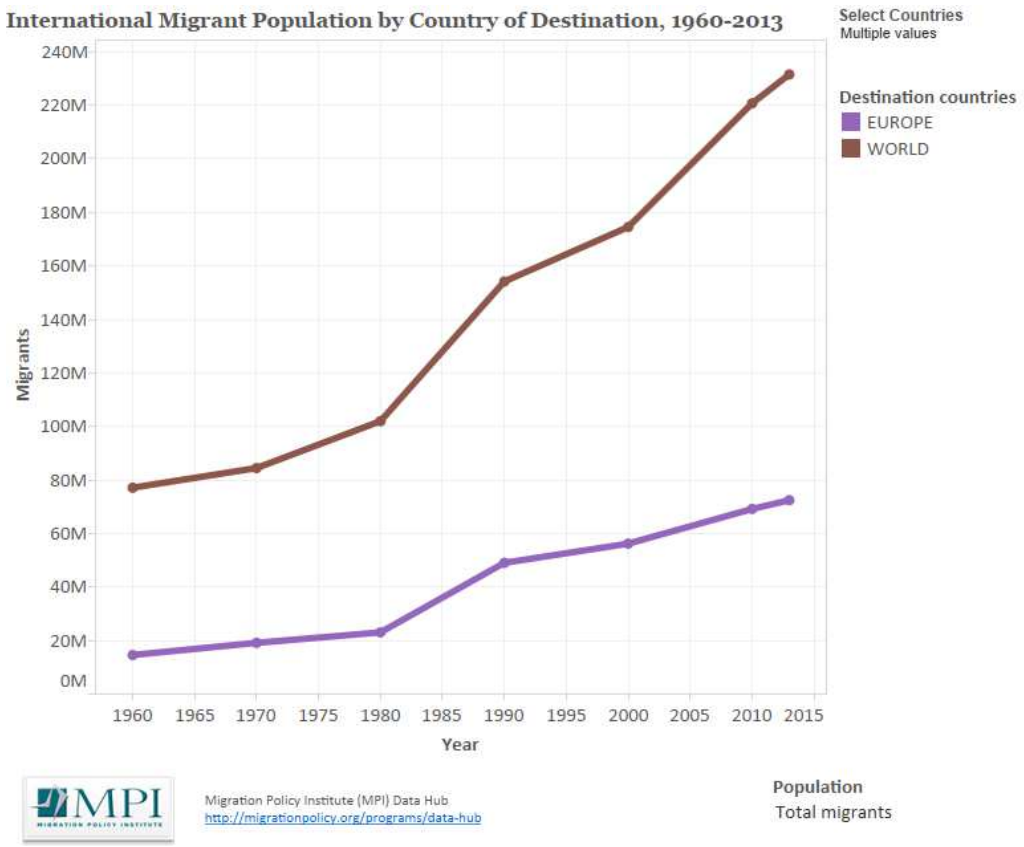

Fig. 1.: Migration in Europe and in the world since 1960, source: MPI

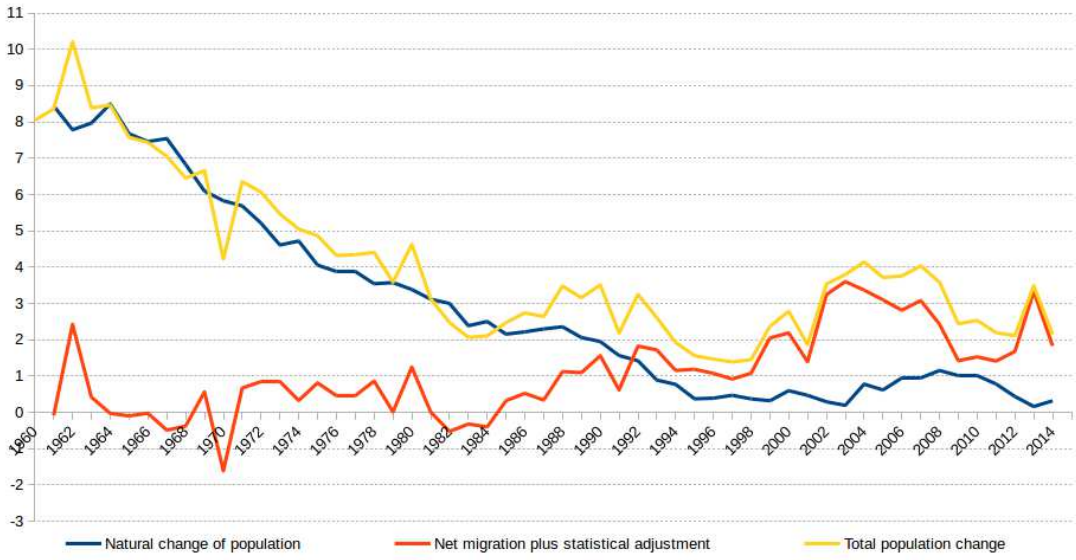

Fig. 2.: Population change by component, EU-28 (per 1000 population), own processing by Eurostat.

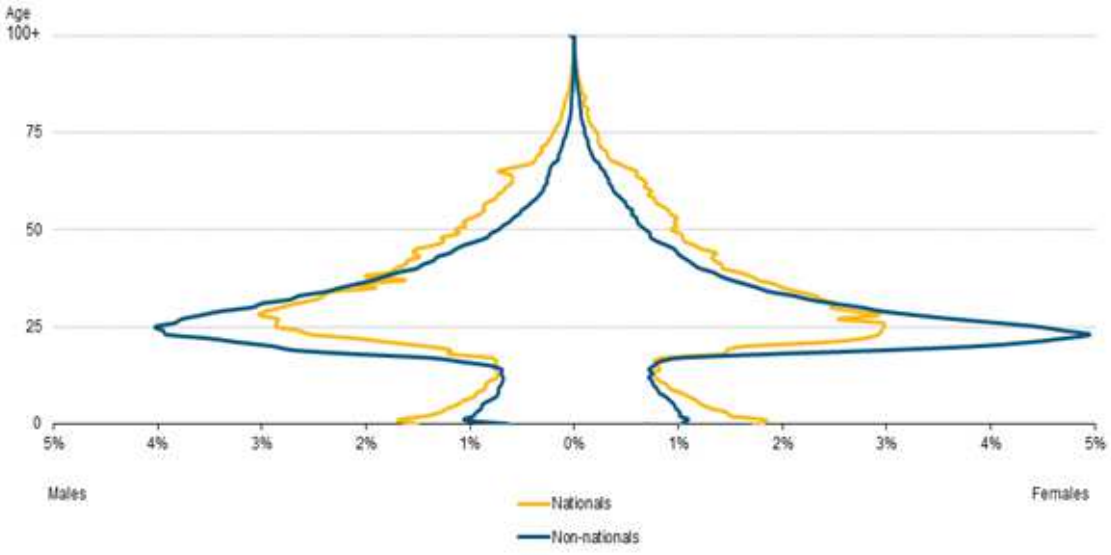
Fig 3. shows an age structure of immigrants by citizenship EU-28 at year 2013. There can be seen a peak of age of immigrants around an age 25 and especially for Non-nationals. This could be the advantage for aging European population.



(*) Excluding Slovakia: detailed data by age are not available.
Source: Eurostat (online data code: migr_imm2ctz)

Fig.3: Age structure of immigrants by citizenship, EU-28, 2013, source: Eurostat

According to Eurostat, most of migrants heading to Europe are from Syria, Afghanistan, Kosovo, Eritrea and Serbia. Statistically closer we can talk about two states from former Yugoslavia that are considered as dangerous by European Union. The most feared Syrians run to Europe from a war site in the number around 122 thousands. A lot of people runs from Afghanistan because after returning of Taliban there is a great danger for people who joint the international community.

In 2005 the Policy Plan on Legal Migration was presented, that marks a "road map", in which the European Commission coordinates with member states to measures such as: presentation of 5 new directives, creating a non-legislative instruments to improve awareness, measures to further improve the integration of migrants into society etc. (MVČR, 2005)

Push-pull theory

To understand all aspects of migration theories it is necessary to explore multiple approaches, for example the push-pull theory based on neoclassical economic theory otherwise known as Macro, which previously described labor migration in the process of economic development. Push factors force the migrants to leave the country from which they originate. These factors include political repression, poor living conditions, demographic growth, low employment opportunities. Economic opportunities and political freedoms, demand for and availability of land are classified into pull factors. As a disadvantage of push-pull theory we can consider a focusing only on the job. The demand for migrants in destination countries is neglected in the theory. (Antropoweb, 2007)

Health human resource migration has traditionally been seen through ‘push–pull’ migration, which tends to exhibit a dualist vision of migration where two separate systems are compared in terms of opportunity and then connected by migration (usually in a unidirectional manner). This approach is also evident in neoclassical gravity models which maintain that spatial difference generates migratory

flows and propensities as part of an 'equilibrium recovering process' (Hart, 1975). However, after decades of Global South to North nurse migration (Organization for Economic Cooperation and Development (OECD), 2007) the inequalities between sending and receiving regions have not 'recovered equilibrium'. Migration, therefore, is not merely the accumulation of rational decision making units moving their respective systems toward some kind of equilibrium; rather migration is berthed within wider power and resource allocation structures. More recent analysis has recognized that global political-economy factors shape HHR migratory flows while using the language of push–pull, (Kalipeni et al., 2012).

The paper (Xu, D.-D., 2015) utilizes sectional data from a 2013 survey of farmers in China's Three Gorges Reservoir area to empirically analyzes the factors influencing migrant workers' choice of employment location.

Theory of dual market

Another theory, which is also based on the pillars of neoclassical economics, is the theory of dual market. It focuses mainly on the demand of the target countries of migration and on the possible recruitment of manpower from developing countries and it does not care about the inequality of wages. Immigrants therefore fill in the missing jobs in selected sectors. Demand for migrants persists even at the moment where in the remaining sectors is high unemployment. This adds the indispensability to immigrants. (Antropoweb, 2007)

World-systems theory

World-systems theory explains the causes and origin of migration by the historical arrangement of market relations of the world system. Like the theory of double market, it operates with the arrival of unskilled migrants with low salaries in wealthy areas. The idea is to expand the capitalist relations of the most successful areas into places where the economic situation is slightly worse and there is more agriculture. (Antropoweb, 2007)

Network theory

During research, Manchester School invented a social network - an innovative method which appeared to be very useful for examining migration from rural to urban locations in Africa. It has been used for research of migrants in Europe after some time. Today it is hard to unify the thesis of network theory, since its importance and practice changed greatly in the history. Sociologist Granovetter found some similarity with the Manchester school when he created the concept of strong and weak ties, which leads to the conclusion that the weak links in social networks are more important as the information is usually spread through weak ties. Its indispensability weak ties also demonstrate in the integration of individuals into teams. (Antropoweb, 2007)

Institutional theory

Institutional theory deals mainly with processes affecting migration and ignores what causes it. Migration here becomes a market where the institutions developed because of migration itself can profit. Theory then watches how institutions stand and to what extent they participate in the institutionalization of migration trends. (Antropoweb, 2007)

Models of integrational politics

Drbohlav (2001) mentions three basic models of imigration policies in a current world.

1. *Discriminatory model* - based on temporary and returnable residence of foreigners, immigrants are only included in certain social areas (labor market), but in others (social welfare, obtaining citizenship) they are denied an access. Foreigners are socio-economic disadvantaged by this inability of entering into many spheres of life. This approach is chosen, for example, in Germany, Austria and Switzerland.

2. *Assimilation model* - expectes, in exchange of rapid acquisition of citizenship, rights and obligations of mainstream society, the immigrant completely give up their original language, with their specific cultural and social characteristics and rapidly assimilats into mainstream society. This approach is closest to the immigration policy of France.
3. *Multicultural (pluralist) model* - promotes diversity of minority from the majority. Immigrants are granted equal rights in all spheres of society, but they are not expected to withdraw from their peculiarities. State instead promotes and develops their specificity. Model applied eg. Sweden and Canada.

Conclusion

Population migration represents a significant dynamic process affecting a substantial long-term development of mankind. Undoubtedly we can expect persistent interest in the European Union as a target area of international migration. Respect for human rights and better living conditions are the main drawing factors that make the EU attractive for migrants. Current demographic trends - an aging population and low birth rate - EU Member States can cause considerable difficulties. Labor markets will lack the staff and social systems will need to provide ever-increasing number of clients. The EU is aware of these forecasts and supports the adoption of common rules in the field of immigration.

Abstract

Electronic resources are no more alien in this era of globalization. Information and knowledge provided in electronic resources is vital and play important elements for survival in information and knowledge society. In achieving the vision of 2020, Malaysian are moving forward to become a knowledge-based society with high skilled economy where intellectual capital, creativity and innovation act as prime drivers for the economic growth. Adequacy of collections is one of the most important factors that fulfilled the needs of user demand. This research examines the factors influencing usage of electronic resources at National Library of Malaysia (NLM). The four factors are individual behavior, library staff, library services and library technology are selected to be the research variables. A total of 218 library visitors participated in the study survey. Findings indicate that the library technology and library staff are having the strongest relationships with user satisfaction. Results indicate that user experience cannot belittled as it would determine their interest and willingness to consistently use the electronic resources provided by the library.

Keyword: Electronic resources, information, library, user satisfaction

I. Introduction

Electronic resources are no more alien in this era of globalization. Information and knowledge provided in electronic resources are vital and play important elements for survival in information and knowledge society. Information and knowledge society is to create, distribute, use, integrate and manipulate the information that is significant to the economic activities. Library plays crucial function in positioning and delivering the information and knowledge to the society. Act as a repository, library serves users with processed information and disseminate to the right users who acquire them. In achieving vision of 2020, Malaysian are moving forward to become a knowledge-based society with high skilled economy where intellectual capital, creativity and innovation act as prime driver for the economic growth. Adequacy of collections (such as books, journals, magazines) is an important factors that fulfill the needs of user demand especially to support their academic or research activities.

National Library of Malaysia (NLM) takes the initiative to give the best services by providing the latest and advance technology to community. The technology behind is the Information Communication and Technology (ICT) where it becomes one of the challenges to NLM in giving the services at par with community's expectation. Embroiled with ICT, electronic resources are the main focus to users to access their information of interest. This medium is indeed make them easier and faster to reach out the information as compared to printed materials. The growing demand on the electronic resources has led NLM to accommodate latest information to fulfill users' requirements. The accessibility to the electronic resources is equipped with latest technology infrastructure such as latest hardware and software, Internet with high-speed broadband connection and learning space with conducive environment. These are among factors that will necessitate users' experience in using the library services. Little works had been published on the user satisfaction at library. Library's main function is as a service provider to the academic community where in order to provide the best service, library should have a periodic assessment where they can evaluate and improve the service to meet user's expectation. Hence this study is conducted to examine the relationships between user satisfaction and selected factors related with electronic resources access in library.

The rest of this paper is organized as follows. The following section reviews the past works on electronic resources, focusing on its concepts and theories, as well as model or framework used. Section III describes the study framework and the research method by giving the details on measurement, population, sampling and data collection approach. Section IV provides the study findings and finally the last section concludes this paper.

II. Literature Review

The rapid growth of information, communication and technologies (ICT), libraries have challenges in holding information resources in traditional and electronic forms to the users. According to Lee and Boyle (2004) an electronic resources is defined as a product and services in digital form that is being marketed. Electronic resources are the product that delivers data in text, numerical, graphical as a commercial product available in digital form includes full text databases, electronic journals, image collections and multimedia products. The electronic information becomes a significant resource to the people to the get the information. The statistic of the usage of the electronic resources has become a hot issue in the field in the library (Wu, 2006).

The electronic resources were influenced by the information literacy and skill in accessing the information of the users. The factors affecting electronic resources access caused of few computers that gave the limitation of the users' access to the electronic resources, lack of awareness of the resources and slow Internet speed. A low level of skillfulness to search data and information to retrieve good information affected of utilization of electronic resources. The issues and problems encounter by respondents in accessing electronic resources are large number of irrelevant information, download delay, failure to find information, inadequate or lack of search skills, high cost of access and difficulties in navigating through electronic resources (Kinengyere, George and Bernard, 2012).

According to Tyler and Hastings (2011) study the growth of online learning and information technology has resulted more access to digital resources than printed resources. Online learning library support for virtual patrons has evolved into the digital or virtual component of the library. The use of electronic resources determines the use of electronic resources, users' skills in handling electronic resources, and the purpose of their use. An electronic resource helps the users to access the information timely and manage the information effectively and efficient retrieval and meeting information needs. The electronic resources are good substitutes for conventional resources for the conventional resources, if the access speed is fast, and more computer terminals are installed to provide access to electronic resources. The librarians have to reallocate more budgets to expand the availability of electronic resources for students and faculty. Furthermore, library professionals should help users to know what high-quality free resources are available on the Internet and how to search these resources more effectively and efficiently. The librarians need to focus more on opportunities for providing training programs for academics on the use of online databases, use of electronic resources and information skills.

III. Research Methodology

This section presents the proposed study framework and methodology used. The proposed framework consists of four independent variables and one dependent variable, as displayed in Figure 1. These variables have been identified from the theoretical review and previous works.

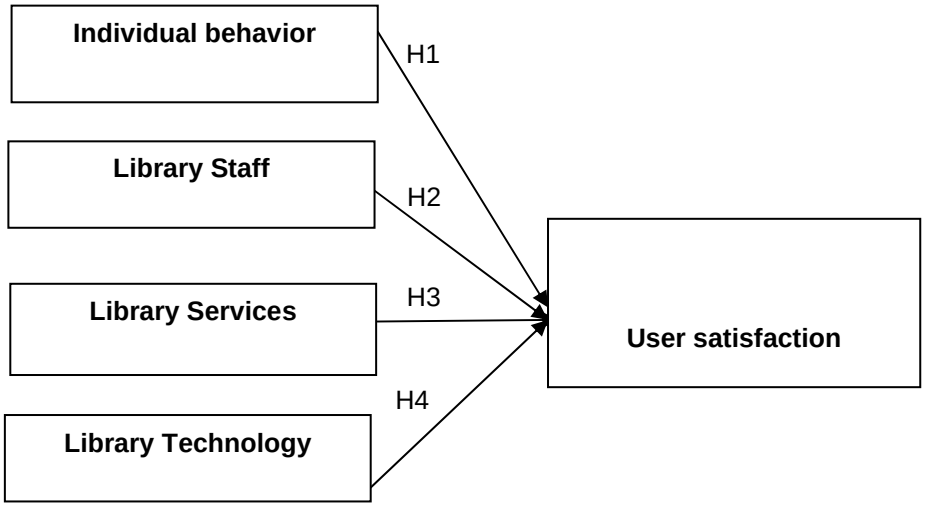

Figure 1: Theoretical framework

The description of each variable used in the study model is given as follows:

A. User satisfaction using library electronic resources

User satisfaction is to measure of how services supplied by a library meet or surpass users' expectation. They focus on the importance of fulfilling users' expectations. According to O'Brien and Toms (2010) user satisfaction is one method of evaluating the effectiveness of library services. Users' feedback help the library to improve services and changes in the service to make it easier to use, more welcoming, or otherwise enhance the user's experience. User satisfaction depends to a large extent on the ability of the library to integrate user needs into the development of the library. Users' satisfaction helps the library to measure the overall quality of the service experiences and improve the services based on the satisfaction feedback from the users.

B. Individual behavior

According to Wilson (2000) information behavior is the totality of human behavior in relation to channels and sources of seeking and use information. Information use behavior consists of the

physical and mental acts involved in incorporating the information found into the person's existing knowledgebase. In this process of information seeking behavior, it involves act to compare, analyze and evaluating the existing and new information. Study from Nadzir and Salim (2013) they mentioned that person who have the knowledge on information seeking behavior has an advantage in finding information to support their study or research process. Information seeking behavior arises as a consequence of a need to accomplish the task which the information is success or failed to determine their need and satisfaction. The improvement of the information literacy will guide them to the right techniques to search the information (Shen, 2010). As claimed by Mohd Nazir, Abd Wahab and Othman (2015), in order to satisfy the information seeking activities, one should possess information literacy skills.

C. Library staff

Library should have professional staff to handle the information and knowledge. Librarian must have qualification to manage the library and its services. The librarian who is positive, proactive, highly motivated and assertive is likely to foster productive relationships with other staff and give them confidence in his or her ability (Steve, 1996).The librarians must have a qualification in library management and experience to handle the library activities (Skretas, 2005). Library staff must be pro-active and aggressive to assist and accommodate the user solved the searching problems. Mamtora (2013) explained that the primary role of the librarian is to provide support information delivery services. In order to meet the user's requirements, librarian should have skill and familiar themselves with various stages of research life cycle and information activities.

D. Library services

The library provides services to the users to search and obtain the information available to users in the library. The library services such as reference collections, borrowing and returning, electronic resources, free Internet access, audiovisual services and others. According to Collison (1952) the information services is library capabilities to provide the vast amount of material contained in the circulation departments and their reserve stocks to meet users' need. According to Skretas (2005) all the equipment and similar technical infrastructure that support the library functions should be appropriate and well function. These included telecommunications and computer networks with appropriate technical support for regular and unexpected conditions to protect library information services. The library should have conducive environment of space, heating or cooling, lighting to attract user entry and provide comfortable for library personnel.

E. Library technology

Technology is the collection of tools, including machinery, modifications, arrangements and procedures used by humans. The library provides the technology to support of new digital environment in this age. The new technology available in the library influence to the users visits the library. University of Michigan (2015) mentioned that Library Information Technology (LIT) is the library division charged with the design, development, management, and maintenance of a flexible and reliable technology environment in the library. Meanwhile, technology support of server-based technologies for the delivery of library services and the maintenance of library management systems. It also helps in delivery of frameworks and systems to support collaborative storage, delivery, and preservation of information resources. Libraries have become technology leaders by providing digital resources into library website. New digital collections are stored in the cloud and mobile applications are developed around them.

Having outlined all the variables' description, the hypotheses formulated for the study are:

1. *H1: There is a significant relationship between individual behavior and user satisfaction.*
2. *H2: There is a significant relationship between library staff and user satisfaction.*
3. *H3: There is a significant relationship between library services and user satisfaction.*
4. *H4: There is a significant relationship between library technology and user satisfaction.*

The data collection approach is via survey method with questionnaire as the survey instrument. The questionnaire is designed based on the previous studies where the corresponding Likert scale is

anchored as 1 for “Strongly Disagree”, 2 (“Disagree”), 3 (“Neutral”), 4 (“Agree”) and 5 (“Strongly Agree”).

The population of the study is the users of the NLM. As being advised by the NLM’s personnel, the total number of NLM users is estimated to be about 550 visitors per day. The users are coming from different background includes student (primary, secondary and higher learning institutions), unemployed, self-employed and those who are having background in teaching, medical, business and others. In this study, the probability sampling techniques was used to select the sample. According to Wilson (2000), probability sampling is a sampling technique wherein the samples are gathered in a process and the population equal chances of being selected to answer the questionnaire. This sampling technique warrants that every individual has an equal opportunity to be selected where it is a characteristic of probability sampling called randomization. The sample is randomly selected among the users who come to the library and the research’s questionnaire is distributed personally. The total sample of this study is 218 respondents.

V. Findings

The study finding begins with users’ demographic profiling. Table I displays the demographic profile of the respondents. Out of 218 respondents, majority is female (56.4%).

Age

Age distribution shows that young adults is prominent with almost covering two third of the sample. While this is as expected, young generations are amongst who are still in study life which made them more frequent to visit libraries. The very low rate for the youngsters (aged below 17 years) could be due to dependency to school’s library which might sufficient enough to support their academic needs.

Table 1: Age distribution

Age category	Frequency	Percent
11-17	7	3.2
18-24	140	64.2
25-31	34	15.6
32-38	26	11.9
>39	11	5.0
Total	**218**	**100.0**

Occupation

In Table 2, the distribution of users’ occupation is given. Majority (67.4%) of the respondents are students, followed by 11.5% from business industry. The results show the involvement of students using library is undeniable due to fulfilling their education needs. Furthermore, it is good to acknowledge about 1% of the sample is unemployed who are still willing to spend their time in NLM. Apart from that, medical background users which composed of only 0.9% of the sample, is expected they are non-regular users of NLM as they may find more relevant materials at their hospitals or specific library.

Table 2: Occupation distribution

Background	Total	%
Student	147	67.4
Business industry	25	11.5
Administrative and secretarial	4	1.8
Teaching	3	1.4
Medical	2	0.9

Unemployed	2	0.9
Hospitality	7	3.2
Transportation	5	2.3
Self employed	6	2.8
Others	17	7.8
Total	**218**	**100**

Total number of visits

Figure 2 exhibits the total number of visit to the library. The intention to capture the frequency is to acquire knowledge on the how critical is the library in users' life routines. It was found that majority of visitor to NLM is between 4-6 visits per month, i.e. about 40%, followed by less than 4 visits (about 38%). About less than 21% paid their visits ≥ 10 times. In overall, the visitors may find the library as part of their needs due to very low frequency detected per month i.e. less than 5 visits. However, there are some visitors who might consider NLM as an important place to fulfill their work/education/life needs, as they become regular visitors within a month.

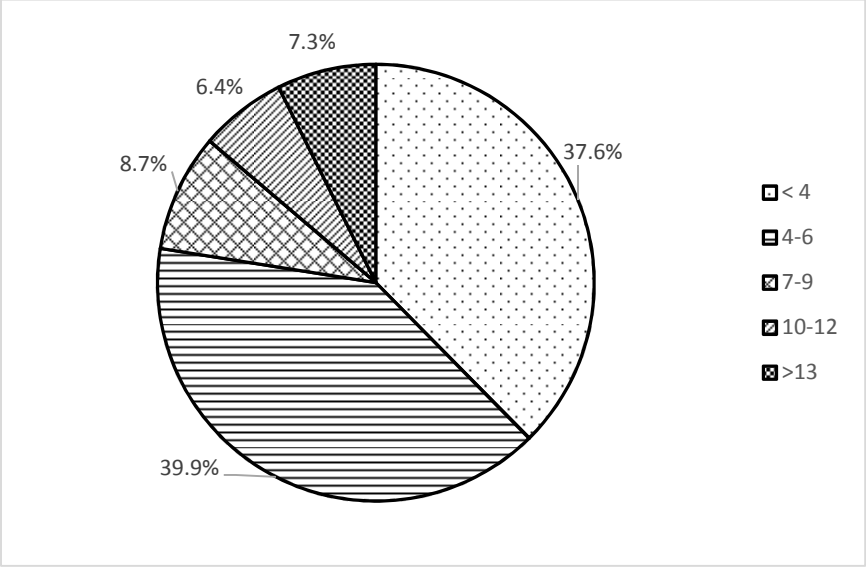

Figure 2: ***The distribution of number of visits to National Library of Malaysia***

Level of Education

Table 3 presents the education background of the respondents visiting the library. It was found that more than three quarter of the total sample are from having higher degree background, which makes about 75%. The respondents could be still engage with the higher learning institution or might have finished their studies. However, observing back the age distribution (in Table 1), it can be drawn that majority of the visitors are students.

Table 3: Education level of NLM visitors

Level	Frequency	%
Primary	3	1.4
Secondary	34	15.6
Diploma/Certificate	65	29.8
Bachelor's degree	99	45.4
Master's degree	17	7.8
Total	**218**	**100**

Types of Electronic Resources Used

Figure 3 depicts the types of electronic resources used by the respondents. Majority is accessing to the Internet (34%), followed by articles (16%). Visitors seem to have interest to access e-newspaper, about 14% of access captured in the findings.

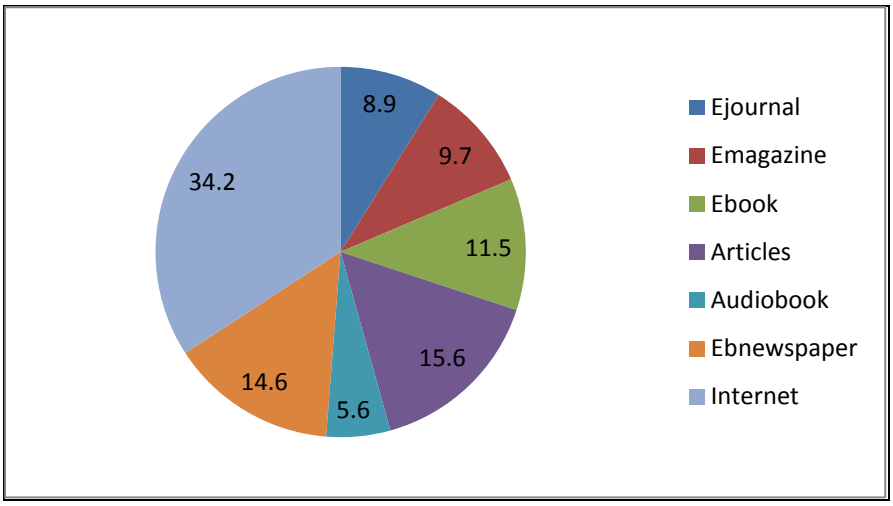

Figure 3: Types of electronic resources used

The following findings present the study variables' statistics properties of mean and standard deviation.

Individual Behavior (IB)

The average of mean score for Individual Behaviour (IB) variable is 3.41, indicates the inclination to positive agreement of the variable. The mean and standard deviation of each item in IB is as exhibited in Table 4. The results show that IB4 and IB5's mean score are among the highest, 3.47 and 3.56, respectively. IB4 relates to "*I know how to evaluate electronic resources for my study*" and IB5 refers to "*I used the electronic resources to solve problems*". The dispersion of each item is small indicating low variability. This early findings suggest the respondents show their positive capabilities in assessing and knowledge of using electronic resources for their intention of use.

Table 4: Descriptive Statistics for Individual Behavior

Item	Questionnaire	Mean	SD
IB1	I have skill to access electronic resources	3.3991	0.94132
IB2	I know the methods use to search electronic resources	3.2844	0.84343
IB3	I know how to select the appropriate electronic resources	3.3624	0.80999
IB4	I know how to evaluate electronic resources for my study	3.4679	0.85404
IB5	I used the electronic resources to solve problems	3.5642	0.93474

4.6.2 Library Staff (LS)

The descriptive profile of this variable is as presented in Table 5 where the average mean score is 3.24. The lowest mean score is 3.18 for LB2 and LB3, relating to questions of "*Library staff are very knowledgeable in electronic resources*" and "*Library staff are very courteous*", respectively. The highest mean score is 3.33, for question "*Library staffs are very helpful in accessing electronic resources*". Based on the finding, early conclusion signifies that respondents inclined to agree with

the items describing the factor of library staff. Moreover, the standard deviation for all items in LS show low variability indicating a strong agreement towards the respective mean scores obtained.

Table 5: Descriptive Statistics for Library Staff

Item	Question	Mean	SD
LS1	Library staff are very friendly and cooperative	3.2202	0.813
LS2	Library staff are very knowledgeable in electronic resources	3.1835	0.844
LS3	Library staff are very courteous	3.1835	0.871
LS4	Library staff are very helpful in accessing electronic resources	3.3394	0.563
LS5	Library staff provide a training for the first timer user to use electronic portal	3.2661	0.720

Library Services (LS)

Table 4.12 provides the summary statistics for library services. The average mean score of LS is 3.34, where the highest is 3.62 ("Library provides conducive learning environment to support electronic resources") and the lowest score is 3.18 ("*Library has conduct adequate promotion and activities to encourage usage of electronic resources*"). The finding provides an early indication that respondents are in positive agreement with the item describing the factor of LS.

Table 6: Descriptive Statistics for Library Services

Item	Question	Mean	SD
LS	Library electronic resources are up to date	3.3165	0.835
LS2	Library provided community space for group learning and study using electronic resources.	3.5275	0.860
LS3	Library electronic resources easily accessible to use	3.3028	0.718
LS4	Library provides adequate electronic resources to meet users' need.	3.2248	0.756
LS5	I am aware the availability of electronic resources in the library	3.2844	0.775
LS6	Library has conduct adequate promotion and activities to encourage usage of electronic resources	3.1835	0.733
LS7	Library provides conducive learning environment to support electronic resources	3.6284	0.866

Library Technology (LT)

Library Technology (LT) variable shows the overall mean score of 3.35. The result of all items is as given in Table 7. The lowest mean score is 3.19 for LT6 ("*Interface of electronic resources portal is friendly*") whilst the highest mean is 3.52 ("WIFI/Internet is accessible to me"). Again, the results

attained are in favour of inclination towards positive agreement to the items as per described in the questionnaire.

Table 7: Descriptive Statistics for Library Technology

Item	Question	Mean	SD
LT1	Library has adequate and latest computers to access the electronic resources	3.3807	0.807
LT2	WIFI/Internet is accessible to me	3.5229	0.932
LT3	Technology equipment support to access online databases	3.4630	0.726
LT4	Library provides latest hardware for computer application for electronic resources.	3.3945	0.712
LT5	Library provides latest software/contents for computer application	3.2798	0.644
LT6	Interface of electronic resources portal is friendly	3.1972	0.653
LT7	Electronic resources easy to download and print	3.2477	0.667
LT8	Electronic resources easy to access remotely	3.4266	0.589

User satisfaction (US)

The variable of User satisfaction (US) shows an overall mean of 3.30, signifies a positive agreement towards the user satisfaction variable, as defined in the study. Table 8 displays the mean scores of all items under US factor. It is discovered that the lowest mean score is 3.21, meant for question of US2 ("*I am satisfied with the convenience to use of the electronic resources*"). The highest mean score (3.38) is relating to question of "*I am satisfied with library services providing electronic resources services to the users that can access remotely*". Again, low dispersion of the mean score is detected for US variable. As indicated by Razilan et.al (2009) user satisfaction is achieved by usability of a system that fits to support the work practice/environment.

Table 8: Descriptive Statistics for User Satisfaction

Item	Question	Mean	SD
US1	I am satisfied with the electronic accessibility efficiency	3.2156	0.640
US2	I am satisfied with the convenience to use of the electronic resources	3.211	0.700
US3	I am satisfied with library staff in helping accessing the electronic resources.	3.2706	0.783
US4	I am satisfied with library infrastructure that support on usage of the electronic resources.	3.3716	0.654
US5	I am satisfied with library electronic resources content that are update and informative.	3.3394	0.580
US6	I am satisfied with library services providing electronic resources services to the users that can access remotely.	3.3853	0.613
US7	Overall, I am satisfied with electronic resources provided in the library	3.2982	0.678

The following section provides the findings in relation to analysis of relationships of the research variables.

Correlation Analysis

In this section, the relationship of the factors is observed through correlation analysis. The correlation approach provides the platform to investigate bivariate linear relationship of variable of interests. The Pearson product-moment correlation test is performed using in SPSS where the results reveal the strength and magnitude of the relationships. The significance of result indicates the statistical evidence of relationship in linear fashion.

The correlation analysis is performed to investigate the bivariate linear relationships between *user satisfaction* and study variables i.e. *individual behavior, library staff, library services and library technology.* All of the study variables possess a positive relationship with *user satisfaction.* Moreover, all are significant at 0.01 significance level. Full results can be referred to Table 9. It exhibits the results where, among the four study variables, the variable of *library technology* shows the **highest** positive relationship with *user satisfaction,* i.e. by having r=0.588. In spite of the fact that it is the highest value, the coefficient indicates only a moderate positive relationship. The weakest relationship is shown by *individual behavior, with r=0.341.*

Table 9: The Pearson product-moment correlation coefficients of all study variables against User Satisfaction

Variable	User Satisfaction
Individual Behaviour	0.341*
Library Staff	0.571*
Library Services	0.468*
Library Technology	0.588*

*Note: *p < 0.01*

The result is as shown in Table 9 where it serves as preliminary finding in examining the relationship between user satisfaction in using electronic resources and selected factors. This initial study implies how crucial the services and technology of a library in fulfilling users' satisfaction.

VI. Conclusion

A study on the relationship between factors of electronic resources usage and user satisfaction at National Library of Malaysia is presented in this paper. NLM plays important roles to provide the collection of knowledge at the national level for present and next generations. Apart from that, NLM has to determine the high-demand of library resources from users to help the Malaysia's people to be an informative and knowledgeable society. This study had revealed that Library Staff and Library Technology play crucial roles in influencing the usage of electronic resources at NLM. Due to this, NLM should play their vital role in positioning themselves to be at par (or more) with users' expectation.

The study findings provide evidence of relationships between Individual Behaviour, Library Staff, Library Services and Library Technology. Although the moderate and weak relationships detected from the data, moving forward, NLM could establish priorities to align with users' expectation and needs for the betterment of their services. Users' experience is far more valuable to NLM to under the radar of users' requirements, needs and interests.

Moreover, in order to promote and encourage users to visit the library, the librarians should be knowledgeable and supportive in guiding users to easily access information of their interest in particular for electronic resources. Information overload may be wasted or underused or can make users confused in choosing the right information. On the other hand, lack of information could lead to insufficiency of guidance. Library staff should play their role in assisting users with basic library information literacy on matters like how to search and retrieve the right information. The advance of

technology provided by the library could attract users to come and use library services. Library, as well as librarian, needs to conduct regular and adequate promotion to ensure all the users recognize the availability of the digital services.

Abstract

This research is conducted to provide a holistic research framework that incorporates key socio-cultural factors affecting knowledge transfer in cross-border M&A. This research will provide empirical suggestion to domestic companies to improve the current management of cultural differences that may be the main reason for the high failure rates of knowledge transfer in international M&A.

A total of 10 domestic companies in Malaysia which had involved in cross-border M&A in the past 5 years participated in this study. The M&A cases were collected from the Thomson One Banker database. At the same time, this research has also cross-verified the selected cases with the Securities Commission and Bursa Malaysia. During company visits, questionnaires were distributed to managers who had been identified through a purposive sampling method based on a list provided by the participating organizations. A total of 200 managers were selected to participate in the survey.

Findings of this research indicate that organizational cultural difference has significant negative influence while relationship and trust has significant positive influence on knowledge transfer in cross-border M&A.

Keywords: Socio-cultural, Cultural difference, Cross-border, Merger and Acquisition.

Introduction

Cross-border merger and acquisition (M&A) are important for organizational growth and development. According Pricewaterhouse Coopers (2011), cross-border M&A is essential for the local organizations to expand their market internationally. Over 80% of the Asia-based senior executives expected cross-border M&A for their companies in the next 12 months with almost 49% also consider to involve in cross-border M&A deal in the next 2 years (PricewaterhouseCoopers, 2011).

Despite current national economic fluctuation, many large organizations in Malaysia are still adopting cross-border M&A to acquire more international consumers, expand market share and offer better value to customers across borders. Cross-border M&A has been recognized as one of the tools for international expansion and diversification among local and government-linked companies (Barrock, 2006). For instance, Telekom Malaysia Berhad (TM) and Maxis communication Berhad, two local telecommunication companies, had ventured abroad by using cross-border M&A to acquire firms in India and Indonesia (Jayaseelan, 2006).

A half or more of cross-border M&A in Malaysia had resulted in a failure and did not achieve a good performance what they expect to achieve in the past (Jansen, 2002). Socio-cultural change is one of the crucial factor of cross-border M&A failure, which is apparently difficult to control and manage by local organizations when M&A takes place across borders and language barriers (PricewaterhouseCoopers, 2011). Thomas and Kummer (2006) indicated that socio-cultural factor may hinder cross-border knowledge transfer in M&A and impede local company from

enjoying more benefits from cross-border M&A. However, at present, there is still a lack of research to investigate key socio-cultural factors affecting knowledge transfer in cross-border M&A. Among the very few previous literature that examine cultural impact on cross-border M&A performance, some previous studies revealed a negative impact of cultural factor on the performance of international M&A (Datta & Puia, 1995; Olie, 1994; Geschwind, Melin & Wedlin, 2016), while some studies identified a positive relationship (Sousa & Bradley, 2015). Other studies indicated either no direct cultural impact on international M&A performance (Efthyvoulou, Bamiatzi, & Jabbour, 2016) or least significant impact on M&A performance (Kanter and Corn, 1994).

Many of the previous cross-border M&A studies were either fragmented (Larsson & Finkelstein, 1999; Deng, 2010) or scattered (Kish & Vasconcellos, 1993). None of the previous study has focused on examining knowledge transfer in cross-border M&A. Therefore, this study is timely and relevant to help improve Malaysian companies' knowledge transfer strategy in cross-border M&A.

This research is therefore conducted to provide a holistic research framework that incorporates key socio-cultural factors affecting knowledge transfer in cross-border M&A. This research will provide empirical suggestion to domestic companies to improve the current management of cultural differences that may be the main reason for the high failure rates of knowledge transfer in international M&A.

Literature Review

Knowledge Transfer in Cross-Border M&A

Knowledge transfer is movement of knowledge among different departments, unit, or organizations rather than individual (Ko, Kirsh & King, 2005; Zhou, Fey, & Yildiz, 2015). Knowledge transfer included transfer of tangible information and intellectual property, expertise, experience, learning and skills (Kalar & Antoncic, 2015). Knowledge transfer across borders in international M&A include the movement of tacit knowledge, which resides in the individual head, and explicit knowledge, which is clearly recorded in reports, documents, articulated and captured among employees in headquarter and international subsidiaries (Veiru & Rivard, 2015).

The following factor may has significant effect on the success of knowledge transfer in cross-border M&A:

Organizational Cultural Differences

The first factor that influences the knowledge transfer in cross-border M&A is organizational cultural differences. Organizational culture is a system and common belief, shared assumptions, values shaped by organizational members (Bauer, Matzler, & Wolf, 2016). According to Kruger and Johnson (2011), organizational cultural is able to support knowledge transfer and facilitate learning among employees in headquarter and international subsidiaries.

Organizational cultural differences may reflect differences in ability to identify, transfer and implement potentially useful knowledge among employees in headquarter and international subsidiaries (Sirmon & Lane, 2004). Organizational cultural differences increase social conflict and have negative impact on knowledge transfer. Organizational cultural differences can also be a source of capability development and value creation on knowledge (Morosini, 1998; Lee, Kim & Park, 2015). Therefore the following hypothesis is tested in this study:

H1: There is a positive significant relationship between organizational cultural differences and knowledge transfer in cross-border M&A.

Relationship and Trust

The next factor, relationship and trust, is also important for knowledge transfer in cross-border M&A. The interaction and knowledge transfer between employees from headquarter and international subsidiaries determine whether both parties can obtain the greatest benefits during the interaction and collaborative alliances (Appelbaum, Roberts, & Shapiro, 2013). International counterpart who is lack of complementary knowledge may cause conflict and instability in alliances, which will eventually affect the efficiency and effectiveness of knowledge transfer process (Lander & Kooning, 2013; Van Gorp & Honnefelder, 2015). Similarly, lacking of mutual trust among international affiliates may result in knowledge silos due to the lack of credibility and trustworthiness in the working relationship across borders (Shah, & Coyne, 2012). Therefore the following hypothesis is tested in this study:

H2: There is a positive significant relationship between relationship and trust and knowledge transfer in cross-border M&A.

Knowledge leadership

The next factor, knowledge leadership, supporting organizational climate for learning, may also affect knowledge transfer in cross-border M&A (Puusa, & Kekäle, 2013; Zhang, 2014). It is essential important for company leader to learn from both past and current decision to ensure organizational effectiveness. A transformative leader can exploit their knowledge in forming international working communities and cross-functional teams after cross-border M&A to enhance employee's commitment and reduce ambiguity in the cross-border collaboration among employees from different countries (Piper & Schneider, 2015). Therefore the following hypothesis is tested in this study:

H3: There is a positive significant relationship between knowledge leadership and knowledge transfer in cross-border M&A.

Employee Job Satisfaction

Cross-border M&A is more likely to be accompanied with job dissatisfaction, which will lead to unwillingness to participate in knowledge transfer, increased turnover and absenteeism. Employees become the key point of the merger failures. Failure to communicate leaves employees to feel uncertain about their future that will cause more anxiety and significant increase the level of employee anxiety, tension and stress (Giessner, Dawson, & West, 2013; Kyei-Poku, & Miller, 2013).

However, if the organization is able to understand their employees' needs and adopt measures to improve their job satisfaction after the cross-border, it will tremendously improve the participation in cross-border knowledge transfer and the success rate of international M&A (Thompson & Phua, 2012; Vetter, 2014). Therefore the following hypothesis is tested in this study:

H4: There is a positive significant relationship between employee job satisfaction and knowledge transfer in cross-border M&A.

Figure 1 depicts the research framework of this study.

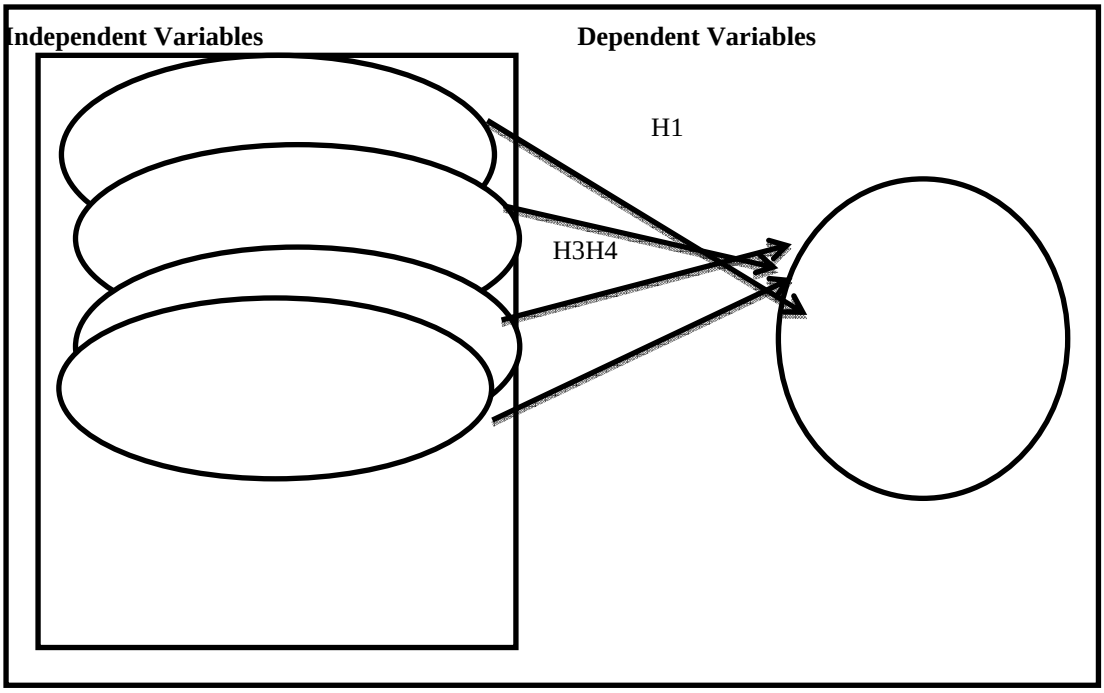

Figure 1: Research Framework

Research Methodology

A total of 10 domestic companies in Malaysia which had involved in cross-border M&A in the past 5 years participated in this study. The M&A cases were collected from the Thomson One Banker database. At the same time, this research has also cross-verified the selected cases with the Securities Commission and Bursa Malaysia. During company visits, questionnaires were distributed to managers who had been identified through a purposive sampling method based on a list provided by the participating organizations. A total of 200 managers were selected to participate in the survey.

The questionnaire is divided into two parts. The first part asks respondents to indicate their agreement or disagreement on 30 items measuring organizational cultural differences, relationship and trust, knowledge leadership and employee job satisfaction using a five-point scale, ranging from 1 (strongly disagree) to 5 (strongly agree). The second part requested information on employees' demographic data, such as age and gender.

Results

Demographics Profile

Table 1 illustrates the demographics profile of the sample. Most of respondents belong to the 20 -25 years old (66.0 %). The second highest percentage from the age group which from 26-30 years old (22.5 %). Meanwhile, the lowest percentage of respondent is from the group between 31-35 years old at the percentage of 11.5 %. There are 94 (47.0 %) of Males and 106 (53.0 %) of Females respondents. The two genders of sample respondents are nearly fairly distributed.

Table 1: Age Profile

Age	**Frequency**	**Percent (%)**
20-25	132	66.0
26-30	45	22.5
31-35	23	11.5
Gender	**Frequency**	**Percent (%)**
Male	94	47.0
Female	106	53.0

Reliability Test

Table 2 shows the values of Cronbach's Alpha for the five variables. Reliability test is used to check the consistency of items in the questionnaire. Cronbach's alpha was reliability coefficient allow to see how close the items related to each other. Table 2 presented the result of reliability test on four independent variables and one dependent variable. The total five variables are reliable to be used in this research. The alpha values ranging from 0.70 to 0.90 are considered acceptable or better for a research, indicating that items measuring each variable are reliable.

Table 2: Reliability Test

Variables	**Number of Items**	**Cronbach's Alpha**
Organizational Cultural Difference	6	0.886
Relationship and Trust	6	0.866
Knowledge Leadership	5	0.751
Employee Job Satisfaction	5	0.831
Knowledge Transfer in M&As	5	0.754

Multiple Linear Regression

Multiple linear regression is used to test the independent and dependent variable. It is used to measure the degree of corresponding of independent variables (organizational cultural difference, relationship and trust, knowledge leadership, employee job satisfaction) towards the dependent variable (knowledge transfer in cross-border merger and acquisition) is analysed.

According to Table 3, organizational cultural difference ($p = 0.000$) and relationship and trust ($p = 0.003$) have significant influence towards knowledge transfer in cross-border M&A. Thus, H1 and H2 are supported. Organizational cultural difference has a significant negative influence on knowledge transfer in cross-border M&A (standardized beta coefficient =-.269) while relationship and trust has a significant positive influence on knowledge transfer in cross-border M&A (standardized beta coefficient = .220). Both factors explain 27.3% of the variance in knowledge transfer in cross-border M&A. However, knowledge leadership and employee job satisfaction are not

statistically significant with knowledge transfer in cross-border M&A (p>0.05). Therefore, H3 and H4 are not supported.

Table 3: Multiple Linear Regression

Model	Unstandardized Coefficients		Standardized Coefficients	t	p	R^2
	B	Std. Error	Beta			
(Constant)	1.469	.278		5.279	.000	.273
Organizational Cultural Difference	-.226	.063	-.269	3.594	.000	
Relationship and Trust	.200	.067	.220	2.995	.003	
Knowledge Leadership	.136	.079	.145	1.722	.087	
Employee Job Satisfaction	.021	.071	.023	.292	.771	

Discussion

The research aims to study the sociocultural factors that affect Knowledge Transfer in cross-border M&A in Malaysia. Organizational cultural difference and the relationship and trust were discovered to be the most influential factors in explaining the knowledge transfer in cross-border M&A.

Organizational cultural difference has significant negative impact on knowledge transfer in cross-border M&A. This result is in line with Bauer, Matzler and Wolf (2016), which discovered that organizational cultural differences has a negative influence in the knowledge transfer where different organizational practices among headquarter and international subsidiaries discourage cross-border knowledge transfer and delay organizational decision making. Efthyvoulou, Bamiatzi and Jabbour (2016) also stated that organizational cultural is important in ensuring the success of knowledge transfer enormous organizational cultural difference lead to organizational performance failure after cross-border M&A. According to Kalar and Antoncic, (2015), if the organizational cultural difference is ignored in cross-border knowledge transfer, it might contribute poor M&A performance.

Therefore, in order to enhance participation in knowledge transfer after cross-border knowledge transfer, organizations should ensure a better understanding of the organizational structure, governance mechanism and business practices immediately after the M&A.

Relationship and trust is another factor, which positively influence knowledge transfer in cross-border M&A. Successful knowledge transfer in M&A required employees in both headquarter and international subsidiaries to build a basic trust immediately after cross-border M&A and then after enhance the trust and relationship between employees across-border gradually. Strong trust and relationship are particularly important in two-way interactions of both sender and receiver to transfer complex explicit knowledge or tacit knowledge.

Therefore, in order to enhance knowledge transfer in cross-border M&A, members in both headquarter and international subsidiaries should be encouraged to form an online community of practice so that they can share their solution to common organizational problems, learn from each other and understand the needs and requirements of each other.

The knowledge leadership is found not significantly important towards the success of knowledge transfer in cross-border M&A. Although Politis (2001) stated that good knowledge leadership is important in M&A to cultivate trust, discover and disseminate knowledge, this study discover that a knowledge leadership is not perceived as an important factor in guiding and motivating employees to effectively transferring knowledge after cross-border M&A. This is probably because most knowledge leaders in the organizations do not use their communication channels optimally and do not focus enough on efficient communication with the employees before

and after cross-border M&A. Since communication is essential during major organizational change such as M&A, it is important for knowledge leader to provide crucial real-time information to employees.

In order for organizations to enhance knowledge transfer across borders, communication from the top to the bottom should be implemented and correct data is essential to be communicated throughout all levels in the organization after M&A in order to ensure that employee know what will happen next. Clear communication from knowledge leader is essential during M&A process as it will effectively reduce the feeling of uncertainty and motivate the employee to be more engaged in cross-border knowledge transfer.

Theoretical Implication

The theoretical framework of this research provides a better perspective on key socio-cultural factors that influence knowledge transfer in cross-border M&A and it contributes to the literature of knowledge transfer in cross-border M&A, which is apparently under-researched.

The findings of this paper raise several interesting issues for future research. Key findings such as knowledge leadership and job satisfaction is not important in influencing knowledge transfer in cross-border M&A, suggest that at least in Malaysian acquisitions, there is the potential for improvements in the organizational leadership and operating performance so that employee will feel more happy and committed working in a big domestic with a lot of international business associates and cross-border M&A activities.

Managerial Implication

The main findings of this study is that organizational differences is crucial in determining the success of knowledge transfer in cross-border M&A. Hence, organizational practitioners should be cautioned of the dynamic nature of knowledge and the complexity to manage organizational difference in sharing and transferring knowledge. Better preparation and understanding of the requirements of the knowledge transfer process is essential before and after M&A. More employees should be involved from the very beginning of the planning of the knowledge transfer process in order to minimize the possible hardships and arising issues that the employees and company may need to undergo after cross-border M&A.

Another implication for practitioners is to emphasise more on motivation and communication of employees after M&A as motivation and communication serve as a virtue base for mutual understanding and trust. Employees will more willing to share and transfer the knowledge across borders if they are treated equally by the leaders and if there is strong relationship and trust among each other.

Le Management Des Universités : Gouvernance Et Compétences Requises

Ramzi Maamer

ECSTRA – IHEC Carthage – TUNISIE

ramzi.maamer@gmail.com

Résumé

Avec les réformes et les restructurations de l'enseignement supérieur mises en œuvre par la France depuis des années, le rôle privilégié des universités publiques dans la production et la diffusion du savoir impose une réflexion préalable sur les compétences des dirigeants universitaires qui sont, au final, des enseignants-chercheurs appartenant à diverses disciplines et ayant des cursus non strictement homogènes.

Manager les universités fait allusion à différentes formes de pilotage, à des mécanismes de coordination, à des modalités d'évaluation ainsi qu'à des méthodes spécifiques de négociation et de prise de décision. La dynamique relationnelle avec les parties prenantes de l'université tiendra compte, entre autres, de l'aptitude des dirigeants universitaires à construire, à développer et à capitaliser leurs compétences acquises et requises en matière de management des universités dans le but de réaliser, d'une manière satisfaisante, toute mission consentie.

Mots clés : Compétence, management des universités, gouvernance, gestion des ressources humaines

Abstract

With the reform and restructuring of higher education implemented by France for years, the privileged role of public universities in the production and dissemination of knowledge requires prior reflection on the skills of university leaders who are ultimately professors from various disciplines and with not strictly homogeneous curriculum.

Manage universities refers to different forms of control, in coordination mechanisms, methods of evaluation as well as specific methods of negotiation and decision making. The dynamic relationship with the stakeholders of the university will consider, among other things, the ability of university leaders to build, develop and capitalize personal characteristics and required skills in universities management in order to achieve their mission in a satisfactory way.

Keywords : Skills, universities management, governance, human resource management

Introduction

La France, comme tous les pays de L'OCDE, a réformé, restructuré et revu ces dernières années son système d'enseignement supérieur. Ces réformes apportent toujours des changements structurels et organisationnels tels que:

- le souci continu d'harmoniser l'architecture du système européen de l'enseignement supérieur avec notamment le système LMD ;

- la pression exercée par la concurrence internationale à travers notamment les classements tels que Shanghai, Financial Times, etc. ;

- le renforcement de l'autonomie des universités avec la mise en œuvre de trois grands principes apportés par la loi Savary de 1984: l'autonomie financière et pédagogique, l'instauration de conseils pour administrer les établissements et la pluridisciplinarité ;

- la politique de contractualisation entre l'Etat et les universités, ce qui a vraisemblablement changé la relation de ces établissements avec l'administration centrale puisqu'on parle désormais de projets d'établissements et de négociation de contrats avec la tutelle.

Ainsi, plus les exigences et les contraintes de l'environnement influencent le paysage de l'enseignement supérieur, plus il était nécessaire de soulever des questions et des réflexions sur le management des organisations universitaires.

L'organisation universitaire publique est une entité qui dispose d'un ensemble de ressources humaines (enseignants et/ou chercheurs, personnel administratif et de support), financières (financement public principalement) et matérielles et est reconnue en tant qu'établissement autonome et non indépendant de l'Etat.

Les universités publiques françaises vivent dans un environnement caractérisé par de multiples changements politiques, économiques et sociaux affectant la relation interactive de gouvernance entre les différentes parties prenantes (organisations publiques, citoyens, acteurs privé, etc.). Celles-ci se retrouvent donc contraintes de s'adapter d'une façon continue et actualisée aux changements notamment par le renforcement du rôle de ses instances consultatives et décisionnelles.

Si l'université est une institution complexe qui a pour mission principale la production et la transmission du savoir, alors comme toute organisation publique ou privée, elle a besoin d'être managé mais avec un mode de coordination et de contrôle bien spécifique. Ce sont les enseignants-chercheurs eux-mêmes qui se retrouvent à la tête des structures organisationnelles universitaires. Ils ont pour rôle principal de manager et de diriger ces organisations mais aussi, selon Châtelain-Ponroy et al (2012), de prendre des décisions, de concevoir des plans stratégiques et de négocier des moyens financiers. Toutefois, comme tout gestionnaire public, ces enseignants-chercheurs se retrouvent, selon Mazouz et al (2015), confrontés à des logiques à la fois bureaucratique et managériale.

Dans une première partie, nous cernerons le contexte de l'enseignement supérieur français en analysant sa spécificité et ses principales caractéristiques. Puis nous présenterons la thématique de la gouvernance en relation avec le management des universités. Il sera question ensuite de décrire la place de la notion de compétence dans le management des ressources humaines et ses implications organisationnelles dans la sphère publique et plus précisément dans celle universitaire. L'intérêt sera porté en particulier à la relation étroite entre compétences des enseignants-chercheurs et leur mission de management des universités.

Contexte de l'enseignement supérieur français

Le système de l'enseignement supérieur français, influencé par le système napoléonien, est un système qui trouve, selon Picard (2009), son origine depuis la création de "l'université impériale" par Napoléon en 1806. Felouzis (2006) explique que cette université fonctionna avec un organe consultatif et un autre juridictionnel qui constituèrent autrefois le conseil de l'université. C'est à partir de cette date que l'université impériale devint une institution nationale laïque avec une autonomie budgétaire et décisionnelle importante puis, par la suite, le ministère publique (1828) et le ministère de l'éducation

nationale (1832) sur décision du gouvernement Herriot. Ce n'est qu'en 1850 que la loi Falloux, en supprimant l'université impériale, donna naissance à l'université de France qui comptait une académie par département.

Lorsque la France a été divisée depuis 1854 en 16 circonscriptions académiques, des facultés ont été créées par le ministère et dirigées par des doyens nommés par les pouvoirs publics. Ce n'est qu'en 1896, notamment avec la loi du 10 juillet 1896 que des universités modernes apparaissent. Elles sont désormais dotées d'un statut légal et reconnues en tant que personnes morales de droit public. La grande réforme apparue suite aux événements du mois de mai 1968 constitue un tournant important dans l'histoire des universités françaises. Ces dernières sont désormais dotées d'un nouveau statut celui d' "Établissement Public à Caractère Scientifique et Culturel" (EPCSC). Un nouveau statut qui remplace les facultés par les Unités d'Enseignement et de Recherche (UER). Cette réforme apporte trois grands principes: l'autonomie (administrative, pédagogique et financière), la participation (élus, représentants du personnel, du corps enseignant et des étudiants, partenaires publics, etc.) et la pluridisciplinarité des universités avec l'apparition de nouvelles disciplines, de nouvelles filières et de nouveaux diplômes. Ces principes ont été maintenus avec la loi du 26 janvier 1984 sur l'enseignement supérieur qui rend les universités dotées de diverses composantes: des instituts, des écoles, des unités de formation et de recherche appelées UFR, des départements, des laboratoires et des centres de recherche.

Avec l'évolution du contexte environnemental de l'enseignement supérieur (avec notamment l'augmentation de l'effectif étudiants, la construction du paysage européen avec notamment l'harmonisation des diplômes, les nouvelles exigences économiques en matière de formation initiale et continue…), de nouvelles réformes sont apparues pour tenter de s'y adapter en apportant à la fois de nouveaux principes, de nouvelles propositions ainsi que de nouvelles lois (plan "Université 2000", plan "U3M"[Université du 3ème Millénaire], loi du programme pour la recherche, loi relative aux libertés et responsabilités des universités, loi ESR [loi pour l'enseignement et la recherche] …)

Gouvernance et management des universités françaises

Selon Bartoli (2005), la gouvernance renvoie à plusieurs facettes et recouvre plusieurs champs disciplinaires. C'est un concept polysémique selon Baron (2003). Shattock (2006) mentionne qu'on parle de gouvernance du moment où il existe des problèmes de coordination entre acteurs qui se déclinent souvent au niveau de l'Etat, de la ville et de l'organisation. La gouvernance d'après Mercier (1999) tient compte de l'ensemble des dispositions qui permettent de s'assurer que les objectifs poursuivis par les dirigeants sont légitimes et que les moyens mis en œuvre pour atteindre ces objectifs sont adaptés.

Il existe souvent un amalgame entre gouvernance et gouvernement. Appliqué aux organisations publiques et plus précisément aux organisations universitaires, les deux notions n'aboutissent forcément pas à la même logique.

Alors que le gouvernement s'intéresse à la répartition du pouvoir exécutif au sein de l'organisation universitaire, aux différentes logiques d'actions relatives à la prise de décision et à la responsabilisation des acteurs concernés par le pilotage et la direction de l'organisation, la gouvernance tend plutôt à considérer plusieurs niveaux de décisions politiques qui intéressent l'avenir, les rôles, et l'évolution du champ d'action de l'organisation en tenant compte de la spécificité des intervenants (parties prenantes) dans les processus consultatif et décisionnel.

En France, la gouvernance appliquée aux universités publiques fait intervenir, selon Braun (1999) des acteurs publics et privés, internes et externes, et d'autres intervenants qui participent tous à la formulation et à la conception de la politique de l'organisation. L'organisation universitaire joue pleinement son rôle de "négociateur" quant aux spécificités contractuelles et aux besoins en ressource.

Les principales parties prenantes susceptibles d'intervenir directement ou indirectement dans la gouvernance d'une organisation universitaire peuvent être divisées en quatre grandes parties:

- Les étudiants, les enseignants et/ou chercheurs
- L'équipe présidentielle de l'université
- L'équipe dirigeante (directeurs des UFR/IUT, des laboratoires, des départements…)
- Le personnel BIATSS et les syndicats

Le mode de gouvernance et de management de chaque organisation universitaire pèsera sur la capacité de cette organisation à réagir aux différents besoins et attentes exprimés par l'ensemble des parties prenantes. Les différentes réformes de l'enseignement supérieur survenues en France ont certes renforcé l'autonomie des universités mais l'Etat reste tout de même la principale partie prenante assurant ainsi son rôle de régulateur, de principal financier et de protecteur du statut public des diverses services proposés.

Le style de management de chaque organisation universitaire tient compte de la capacité de l'équipe dirigeante à partager les expériences, les bonnes pratiques et à requérir à des modes de coordination et de contrôle adaptés au niveau de compétence et de responsabilité des différents acteurs intervenants dans la sphère décisionnelle et opérationnelle de l'organisation. Ainsi, l'organisation universitaire évoluera et réagira d'après Saide (1992) sous l'impulsion de formes diverses de pilotage, de projets et de visions stratégiques, de modalités spécifiques de négociation et de prise de décision mais aussi de l'aptitude des managers universitaires à construire, développer et capitaliser les compétences acquises et requises en matière de management des universités.

Compétences requises en management des universités

La compétence en GRH

L'étude de la compétence revêt, selon Minet et al (1994), une importance particulière en sciences gestion et plus particulièrement en Gestion des Ressources Humaines (GRH) telle que constatés également par Arnaud et Lauriol (2002) et Dietrich (2010). Elle se trouve depuis les années 1980 non seulement au cœur des discours des dirigeants et des directeurs des entreprises publiques et privées mais aussi, selon Dejoux (2001), au cœur des préoccupations des chercheurs et des praticiens. Il s'agit d'un concept considéré comme une disposition à agir suivant un processus bien déterminé. Selon Aubret (2002), la compétence peut être individuelle, collective ou organisationnelle et révèle, d'après Lichtenberger (1999), les capacités d'un individu à répondre aux exigences de performance d'une organisation.

Zarifian (1999) note que l'avènement du modèle de la compétence en GRH remet en cause les notions de poste et de qualification. Une analyse des concepts de qualification et de compétence réalisée par Wittorski (1998) montre que cette dernière dépasse largement le simple clivage entre les deux notions citées surtout lorsqu'on expose, à la lumière des travaux d'Oiry (2005), les « points de repères » permettant de définir chaque concept et ce à partir de la littérature qui lui a été consacrée. L'individu dans l'organisation n'est donc plus réduit à ses seuls savoirs et savoir-faire certifiés par des diplômes ou par d'autres moyens de reconnaissance, mais avec la compétence, on prend en compte plusieurs autres caractéristiques, niveaux et dimensions permettant à l'individu de répondre aux besoins d'une quelconque activité professionnelle. Cette action respecte généralement deux principales conditions : l'implication dans une activité de travail et l'employabilité résultant de cette action. De ce fait, chaque

individu est capable, selon Le Boterf (2000), de construire une compétence et réunir les conditions favorables pour la réaliser, la préserver et la développer continuellement dans chaque situation de travail.

Notre intérêt pour les compétences construites et développées par les enseignants-chercheurs dans leur mission de management des universités est défini à partir du fait que ces enseignants-chercheurs n'ont pas forcément été formés à ces genres de mission ou n'ont pas les compétences requises pour les réaliser efficacement. Mais en contre partie ils emploient certaines prédispositions afin de construire de nouvelles compétences ou pour développer des compétences déjà acquises. La construction et le développement de ces compétences ne sont pas le fruit du hasard ; il existe une formalisation voire une relation étroite entre les compétences d'un individu et les attentes professionnelles de son poste de travail. Selon Le Boterf (2000), l'exercice d'une compétence ne peut se réaliser sans maîtriser un certain nombre de connaissances indispensables, de savoir-faire techniques, de comportements et traits de personnalité adaptés. L'apprentissage, tel qu'analysé par Argyris et Schön (2002), joue ici un rôle important dans l'appropriation et la construction de ces compétences.

Un individu en situation de travail s'approprie tout d'abord un certain nombre de savoir et connaissances. Comme analysé dans les travaux de Nonaka (1991) et Reix (1995), les connaissances peuvent être tacites (difficiles à formaliser ou à communiquer car elles ont un aspect personnel) ou explicites, c'est à dire capturées dans les livres, les monographies, les plaquettes ou même à travers la formation pendant les séminaires, les stages ou autres…comme le montrent Ballay (2002) et Bouvier (2004) dans leurs travaux de recherche. Ensuite, il s'agit pour l'individu de reconvertir et de développer ces connaissances tacites et explicites suivant un processus de création de connaissances qui tient compte, selon Nonaka et Takeuchi (1995), de quatre procédés de conversion :

- **La socialisation** (reconversion des connaissances tacites en d'autres connaissances tacites grâce à l'apprentissage et le partage d'expérience) ;
- **La combinaison** (reconversion des connaissances explicites en d'autres connaissances explicites par le biais d'un langage commun et de divers mécanismes de communication) ;
- **La formalisation** (transformation et consolidation des pratiques en un discours formalisé prêt à être communiqué)
- **L'intériorisation** (appropriation par un individu/groupe des connaissances explicites pour les transformer en savoir-faire)

Cette analyse nous permet de montrer que tout individu a des prérogatives pour s'approprier les connaissances dans le cadre d'une situation de travail. C'est le caractère construit de cette appropriation qui lui permet ensuite d'acquérir de nouvelles compétences. L'individu dans l'organisation, quelle soit publique ou privée, n'est pas réduit à ses seuls savoirs et savoir-faire certifiés et reconnus par des diplômes ou par d'autre moyens de reconnaissance mais, avec la compétence, on prend en compte plusieurs autres caractéristiques et dimensions qui permettent à cet individu de répondre aux exigences d'une activité professionnelle donnée.

Compétences distinctives des managers universitaires

En France, les enseignants-chercheurs, parmi ceux qui ont été élus, s'occupent de la présidence des universités ou de la direction des composantes. Ces enseignants-chercheurs accèdent ainsi à des missions managériales universitaires et ils se retrouvent pour un temps, comme le souligne Musselin (2001, 2009), en position de manager public. Dans l'exercice de leurs missions, ils se retrouvent généralement confrontés à certains obstacles :

- **Structurels** (mauvaise compréhension des rouages administratifs, formation préalable quasi-absente, contrariétés bureaucratiques…),

- **Professionnels** (manque d'expérience, absence de maîtrise de certaines conduites managériales…)

- **Comportementaux** (conflits internes, jeux de pouvoir, influence du leadership…)

La réalisation d'une mission managériale universitaire requiert la maîtrise et l'adoption de certaines compétences spécifiques surtout lorsque l'accès à ces types de mission se fait à la suite d'un processus électif qui ne s'appuie forcément pas sur les qualités et aptitudes managériales de l'élu mais plutôt sur son parcours politique, académique et institutionnel à l'université. De ce fait, il n'est plus possible aujourd'hui d'élire des dirigeants universitaires uniquement sur des performances académiques mais plutôt, et comme le souligne Demichel (2000), sur la base de compétences managériales acquises.

Les compétences des enseignants-chercheurs dans le contexte managérial universitaire sont un sujet en action et en perpétuelle construction. Elles ne sont pas directement observables et elles dépendent fortement de leur contexte. Elles sont acquises généralement par le biais de quatre principales sources:

- **La discipline ou la spécialité de l'enseignant-chercheur** : ce sont les années de spécialisation ainsi que les différentes tâches pédagogiques et de recherche entreprises durant la réalisation du travail. Cet apport procure aux enseignants-chercheurs des compétences intellectuelles, interpersonnelles et relationnelles qui sont à la fois générales et spécifiques. Lorsqu'elles sont spécifiques, ces compétences se rattachent surtout à la spécialité de l'enseignant-chercheur (par exemple les enseignants-chercheurs en sciences de gestion auront des compétences spécifiques en gestion…).

- **Les expériences professionnelles extra-universitaires** : certains enseignants-chercheurs ont (eu) la possibilité par exemple de diriger une association, d'assumer une responsabilité ou une mission dans une entreprise privée ou publique, etc. C'est un apport qui accentue la capacité d'avoir vécu des situations professionnelles pouvant être proches de leur mission managériale universitaire.

- **Les responsabilités universitaires administratives et/ou managériales** : l'enseignant-chercheur qui a précédemment assumé une mission administrative ou managériale dans une organisation universitaire est un terrain favorable de se sentir familier avec certaines situations ou pratiques professionnelles semblables. Cela accentuera la capacité de l'enseignant-chercheur à détenir un certains nombres de compétences supplémentaires et complémentaires aux compétences de base (un président d'université qui a été précédemment directeur d'UFR a déjà acquis une expérience précédente en matière de pratiques managériales universitaires).

- **Le transfert et le partage de compétences entre collègues** : le transfert et le partage de compétences sont considérés parmi les mécanismes d'acquisition des compétences entre enseignants-chercheurs eux-mêmes ou entre enseignants-chercheurs et agents administratifs.

Avec un tel portefeuille de compétences que peut détenir un enseignant-chercheur, la construction de nouvelles compétences à mobilier et à développer demeure l'étape la plus importante et la plus décisive pour l'efficacité de la réalisation de sa mission managériale à l'université.

L'enseignant-chercheur construit et développe ainsi trois catégories de compétences:

- ***Des compétences formalisées*** : qui sont produites dans l'organisation universitaire en faisant référence au cadre législatif, au règlement intérieur, aux usages et habitudes organisationnelles...

- ***Des compétences opératoires :*** qui réunissent les savoirs pratiques et les savoirs élaborés dans l'expérience. L'enseignant-chercheur exploite ces savoir-faire construits qu'il mobilise et développe dans l'exercice de sa mission managériale.

- ***Des compétences managériales :*** qui se réfèrent généralement à la capacité de l'enseignant-chercheur à se comporter comme un « manager » d'une organisation.

Ces trois catégories de compétences sont construites et développées tout au long de la carrière de l'enseignant-chercheur, elles sont plus utilisées et accentuées lors de l'exercice d'une mission managériale universitaire.

Conclusion

Les compétences des enseignants-chercheurs dans le contexte managérial universitaire sont un sujet en action et en perpétuelle construction. Elles ne sont pas directement observables et elles dépendent de leur contexte.

Ces compétences sont interpersonnelles (aptitudes communicationnelles, aptitude à la conduite d'équipe, emploi de certaines attitudes et traits de personnalité). Elles sont aussi politiques dans la mesure où un dirigeant universitaire sait exercer son autorité, se comporter comme un leader pour exercer un rôle dans l'organisation, prendre les décisions adéquates et s'assurer de leur application et aussi donner un sens à tout changement organisationnel dans l'université.

Si les universitaires n'appartiennent forcément pas à une même discipline, n'adoptent nécessairement pas les mêmes pratiques professionnelles et organisationnelles dans l'exercice de leur mission de management des universités, alors il serait judicieux de penser à des formes d'accompagnement et de développement appropriées pour atteindre et valoriser les potentialités managériales recherchées.

L'analyse des compétences des enseignants-chercheurs qui occupent des postes managériaux dans les organisations universitaires peut servir à s'interroger sur la nature et les exigences de ces postes en termes de compétences professionnelles et d'attentes managériales. Face aux nouvelles exigences et évolutions environnementales, les pratiques managériales changent et de nouveaux modes de travail apparaissent. Ceux-ci remettent en cause les composantes même des compétences actuellement acquises par ces managers universitaires et requièrent probablement des compétences distinctives et différentes dans le but de consolider la place de leurs organisations universitaires dans un contexte de compétitivité internationale.

Abstract:

Modelling, creating and identifying the leader typology facilitate leadership support and builds leadership sustainability. Such a model creates a cycle of ongoing leadership development that continuously manages and sustains the future leader. The model proposed in this paper presents a primary mechanism of how leaders shape culture. The cultural diversity of businesses requires that management makes sure they understand cross-cultural boundaries. A survey was submitted to persons involved in small and medium business owners to identify a leader model and his capacity of adaptation with the new trends in management culture. The factors influencing managerial styles and behavior were identified: external and internal factors, decision-making factors for leading and factors which can affect their behavior and attitude in organization. The results indicated that leader and staff organization approaches to a specific model in function of their culture and the results obtain are useful to characterize the work of small business owner-managers. The comprehensive model proposed by authors will help local organizations and their leaders to understand the current market conditions as well the business culture. The paper can contribute to the development of sustainable leadership in other countries and establish a new orientation in organization culture management.

Keywords: sustainability**;** leader model; leadership; cross culture model; **s**mall business; management culture

1. Introduction

The cultural models of Peterlin et. al (2013) and Grooms et. al (2011) are very relevant in today's global world. The GLOBE project (Global Leadership and Organizational Behaviour Effectiveness Research Project) is the largest study of international leadership across cultures (2015).
The results of the GLOBE project support the argument that leadership values, or the strength of the relationship between leadership values and what is viewed as effective leadership, can be identified from the cultural dimensions (Javidan et. al. 2006).
The information from GLOBE (Project Globe, 2015) can help leaders explain their approach to leadership in cultures other than their own, identify how their approach is similar and different from leadership approaches typically seen as effective in another culture, and understand why they prefer a particular leadership approach.
Through this data-driven approach, the project teaches about leadership across cultures. Matthews and Thakkar (2012), present an interesting model of the impact of globalization on cross-cultural communication: 4 C's Global Leadership Model. The new model consists of four key elements: communication, creativity, conflict and connectivity. The novelty lies in the support of innovation and management change.
The model provides a support for organizational leaders who are working with multicultural teams, to compete in the ever-changing global environment. Hamel (2009) introduced a new concept regarding the reinvention of management and definition of a new democracy of information for organizations in a turbulent world. He identifies 25 moon shoot factors that are important for managers in implementing innovation in organizations. Sustainability is defined by Steiner and Posch (2006) as humans surviving indefinitely into the future with a reasonable quality of life. The three dimensions of sustainability are:

economic, social and ecological development. Although sometimes the ecological/environmental dimension of sustainability is presented as the core discussion, the three dimensions must be equally important to leaders, and it is necessary to equip them with the knowledge and skills that will enable them to function in a business environment that has sustainability as its core value. Globalization creates a need to understand how cultural differences affect leadership performance and leaders need to become competent in cross-cultural awareness and practice. Cross-cultural competencies for leaders are:

1) To understand business sales and the cultural environment;
2) To understand economic trends and technologies;
3) To be able to work simultaneously leader- staff:
4) To be able to adapt to other cultures.

The dynamic quality spiral provides an important constraint in the evolution of sustainability, demonstrating that just like sustainable development, sustainable leadership represents a process and not an end.

1.1. Leadership vs. Culture

There are three required elements of leadership: the ability to influence, a common goal or vision, and followers that are willing to work toward the vision. However, even with all three elements in place, there is no guarantee that effective leadership will automatically follow. Even in an ideal organization, where a culture has traditional values, norms, and practices, it is still not easy to be a leader. Leaders achieve little if the culture does not allow them to influence staff to work toward a common goal. Leadership cannot exist in the wrong culture.

In the literature there are articles by Northouse (2007), Newstrom and Pierce (2010 and Druker (1996) on leaders and the leadership role. In sustaining societal change, Druker (2004) focused on visionary leadership with an emphasis on leaders of the future. Hargreaves and Fink (2004, 2015), define their critical principles of sustainable leadership as the ability to:

1. create and sustain learning process ;
2. ensure success over time;
3. sustain the leadership of others;
4. address issues of social justice;
5. develop rather than deplete human and material resources;
6. promote environmental diversity and capacity;
7. actively engage with the environment.

Today's leadership in a global society requires an educational model. Ceulemans et al. (2015), Marcote et al. (2015), Velasco et al.(2014) propose a cross cultural evaluation and report a model for organizational management based on attitude changes for sustainable development. Vann et al. (2006), Hamel and Breen (2007) mention the future of management where leadership has an important role. Leadership sustainability is the ability of leaders to recognize the intricate systems interwoven with human values that promote sustainability.

Leadership is important for an organization's success in the globalized economy, however leaders have not been trained, educated or prepared to deal with the complexity and environmental reality. Hofstede's work (1991), presents an approach to cross cultural management. The model is important because it bridges the connection between companies in different countries that are now in a global market and multinationals, where difficulties and cultural feedback can be different. Culture can be defined as dynamic in the sense that it changes over time and this change in culture could lead to conflict. According to Adler (1986), a cross cultural management model explains the behaviour of people in organizations around the world and shows people how to work in organizations with employees and client populations from many different cultures.

2. Leaders for Sustainability

2.1. What qualities does a sustainable leader need to have?

The literature research by Fullan (2001) and Hargreaves (2005) suggests the following seven key characteristic traits and styles in distinguishing the leadership approach taken by individuals tackling sustainability issues:

- Systemic, interdisciplinary understanding;

- Emotional intelligence and a caring attitude;
- Values orientation that shapes culture;
- A strong vision for making a significant difference;
- An inclusive style that engenders trust;
- A willingness to innovate and be radical; and
- A long-term perspective on impacts.

Leaders are facing financial and structural challenges, and represent a sustainable management signals to investors, employees, and customers that a business is stable and the leadership has a long-term vision, drawing on state-of-the-art practices. Leaders stand at the intersection of leadership, culture and brand. They need to be trained to lead stakeholders and not just to respond to crises, with one foot in the investor world and the other deep inside their culture in order to be able to manage the triple-bottom line, which means overseeing social issues. The model proposed in this paper presents a primary mechanism of how leaders shape culture:

1) Problem structure: How or what is the structure of the problem?
2) Organization goals: How the employees share the organization goals? Are they involved in solving problems?
3) Subordinate conflicts: Is there conflict among subordinates over preferred solutions?
4) Subordinate infrastructure: How subordinates have a supporting infrastructure to make a decision?

According to Fullan (2005), sustainability is the capacity of a system to engage in the complexities of continuous improvement that are consistent with profound human values.

2.2. Why Sustainable Leadership Matters

According to Hargreaves and Fink (2005), leaders develop sustainability through the way they approach, commit to and protect deep learning in their organizations. These authors consider the first principle of sustainable leadership to be leadership for learning and caring for others. Today's leaders need to adapt to leading and managing people from different cultures. Today's businesses are complex entities. The cultural diversity of businesses requires that management makes sure they understand cross-cultural boundaries. Modelling, creating and identifying the leader typology facilitates leadership support and builds leadership sustainability. Such a model creates a cycle of ongoing leadership development that continuously manages and sustains the future leader.

2.3. How we can sustain sustainable leadership?

For a manager, the comprehensive model proposed in this paper, helps to identify gaps in the change management process and to provide

- effective coaching for his/her employees;
- diagnosis of employee resistance to change;
- a learning tool in teaching change management;
- a framework for change management teams to evaluate change management plans;
- help for the employees through the change process;
- successful action plans for personal and professional development during change;
- a transition plan within change management for his/her employees;
- a track of progress and an understanding of gaps in any existing change program.

A broad research area called organization cultures is carried out the comprehensive model of this paper within cultures, which maintains that until now organizations have mainly been studied in terms of organization as an economic system.

Grooms and Reid (2011) states that leadership sustainability is the ability of leaders to recognize the intricate systems interwoven with human values that promotes sustainability. Leadership is a complex process involving three dimensions: the leader, the employee and the demands of the situation. Speaking about the world of business with Edersheim (2007), Peter Drucker (2004), who is considered to be the father of modern management, and a respected management thinker in his own right, focused on the visionary leadership role in sustaining societal change with an emphasis on leaders of the future. The communication barriers include culture, technology, language, workforce, and environment. Culture values have an important effect on how the leader management run an organization. Each culture model takes into consideration time, space (country), business structure (state or private) and action type of

activity. Time in every culture depends on its traditions. Time can influence the history and traditions of a company. Culture itself is a shared set of assumptions, values and norms of a group of people which helps them to prioritize what they are going to do and how they are going to get things done. It makes it easier to get things done within one's own culture than working across cultures. The strategic development for a comprehensive cross model considers the following stages of management culture changes from a traditional culture as an inside culture to organization to a future culture as an outcome culture, which is necessary for organizations that have to communicate across cultures to ensure that their message is understood (Figure 2).

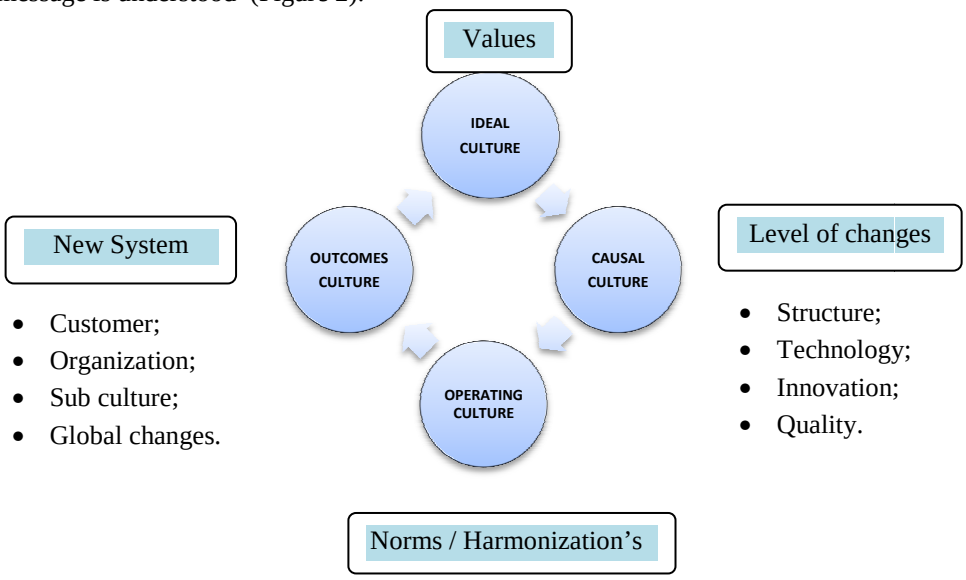

Fig. 2. A strategic approach to cross culture in organizations Source: The authors

From quality management point of view, the role of leader is important because the translation from quality management to the cross cultural model can be performed following the stages: *vision* – ideal culture with values of global culture, *mission*- traditional culture with specific structural changes, technology, innovation and quality, *politics*–operating culture adapted with the norms and harmonization of other cultures and *strategy*–outcome culture with new system for customers, organizations, subcultures and global changes. Culture also helps to define the group, because cultural intelligence is key to the success of todays cross cultures, cross borders, cross organization workers.

3. Research and Methodology

This article looks at the applicability of certain aspects of sustainable leadership to the circumstances surrounding small and medium enterprises in Maramures County, Romania.
The article examines the distinctive challenges encountered by directors of small organizations experiencing problems in pursuing sustainable leadership. The reason for our interest in leadership of small and medium enterprises located in urban and rural areas has been explained in the contextual background of the article's focus on sustainable leadership, identifying the variables which can influence the leader's characteristics and behavior and be capable of changing it when there is a comprehensive model for leader and leadership. A total of 250 people participated in the research, with different education backgrounds, and involved in different activities. The survey developed for this study consisted of 24 items that were rated according to five points. Each of the items assessed one of the cultural measurements of acceptance, conflict, individualism, risk, or sharing. The survey was carried out between June-July 2015, in Maramures County, Romania, in several cities: Baia Mare, Sighetul Marmatiei, Cavnic, mining cities affected by the economical crises and which are under transition to a surviving solution. The study identified the variables influencing the leader model thus enabling it to be adapted to a future global market.
The survey was structured as follows:

- **Part 1**. Identifying the characteristics of respondents involved in economic activities, on age, gender, education, work experience;

- **Part 2**. Collecting information on the business type and the familiar field of business for respondents. period of employment with the same business, size of business, type of business (services, manufacturing, retail, structure of legal business state, private, SMEs, relation between business manager, employee.
- **Part 3**. The structure was created to determine the leadership profile, and establish the variables that could influence the leader profile. Part 3 of the survey contained 15 items, designed to obtain the leader model depending on factors of influence. For a better understanding of the structural factors of influence, it was necessary to create four groups of factors: internal factors, decisional factors, affective factors with internal impact of influence, affective factors with external influence questions.

Leadership involves an influencing process between leaders and followers to ensure the achievement of organizational goals. The items were characterized using a Likert scale with values from 1=strongly disagree to 5=strongly agree (Allen and Seaman, 2007). The research was designed to evaluate the effect of an experimental leadership model for Romanian leaders, based on the development of sustainable competencies as opposed to a traditional leadership model.

3.1. Principal Component Analysis

Reynolds and Valentine (2011), Osvald et al. (2006) defined the leadership capabilities for a leader profile, which is why the research focused on a new leader model adapted with the new global competition.

The model predicts the variables of leader personality characteristics and indicates non significant relationships. Increasing cultural flexibility is an important development goal in those global leaders who frequently take business trips to different countries or those who may move abroad in the future. There are various effective ways to build positive cultural capital

1. Using cross functional teams;
2. Creating a shared vision;
3. Coaching;
4. Using democratic decision making processes.

Another dynamic component companies seek to develop in their future global leader is the ability to manage, to be open to new solutions, innovation, and differences (Figure 3).

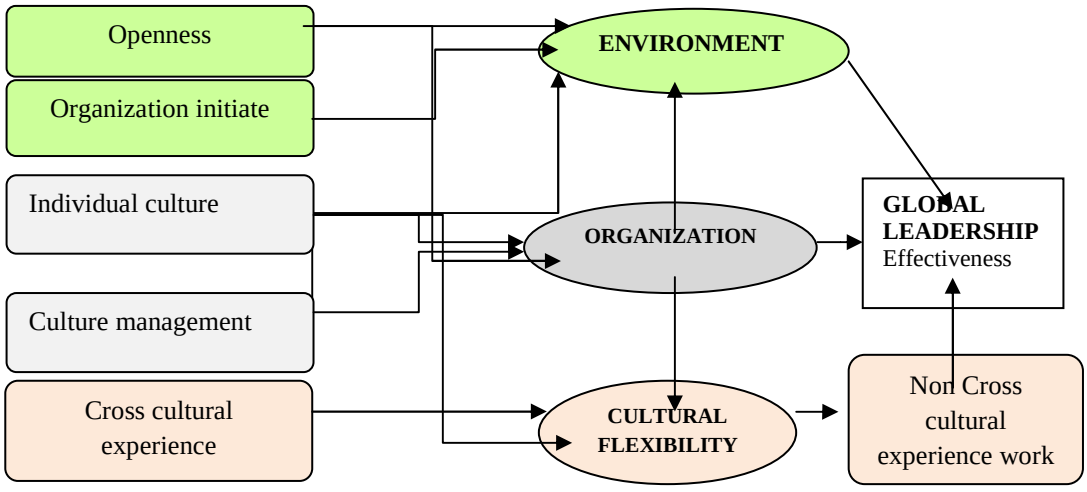

Fig. 3. A Comprehensive Leadership Model. Source: The authors

The concept of sustainable development needs to be integrated with the politics and practices of management across organization borders using personal examples. Woods (2004) evaluated cross cultural management performances and established that culture has many areas of impact with management:

- The Cultural West Industry for East countries:
- The role of culture training;

- The organizational culture.

Other significant performance elements for Romanian leaders that should be uniquely tailored to the cross-cultural organizational context under the strong influence of west-east culture should be taken into consideration. Bell and Pavitt (1993) mention technological accumulation and industrial growth as contrasting elements between developed and developing countries.

For Romania which belongs to the eastern market and is a transition economy, the differences between the western and non western culture are:

- **Western culture**: individualism, time is money, achievement, equality, respect for results, internal self control, acting by doing;
- **East culture:** collectivism, hierarchy, humanistic, respect for elders, collaboration, external control, formal relationships

Leadership plays a critical role in sustainability through its vision, mission and by making strategic decisions for the organization. Hammer (2004) management change theory it is a necessary especially today when cultural values of Romanian organizations are oriented to the west culture and are in a turbulent market. Also the communication and the impact of leaders with subordinates are important for a comprehensive leader model can be drawn as shown in Figure 4.

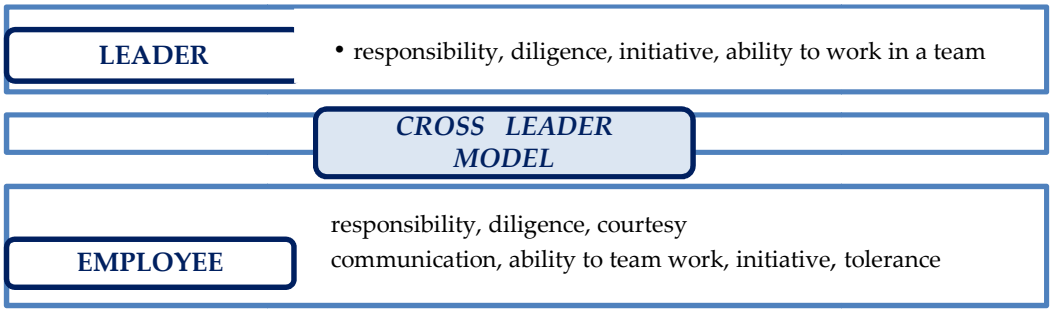

Fig.4. A Comprehensive model for leader /employee characteristics, Source: The authors

Tagred (2012) reports cross cultural differences in organization management, that's the reason of the actual research to identify the necessity for deep changes for Romanian organizations, to establish a comprehensive leader model. Abrudan (2012) stated that concrete results in organizations management sustain the idea that culture can be considered environment as the primary development for organization. Leadership is a complex process involving three dimensions: leaders (inspiration), employees (guide) and the motivation (Figure 5).

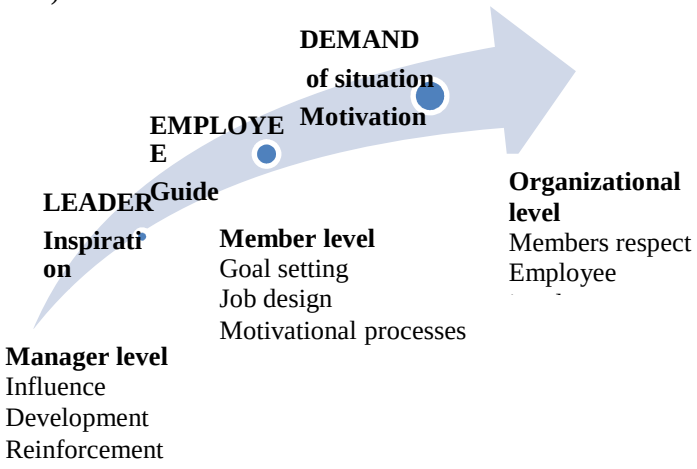

Fig. 5 A Comprehensive model vs. Leader Model. Source: The authors

There are many challenges that would-be leaders face: understanding how to deal with people, identifying goals, maintaining energy and dedication toward a brighter and better future.

4. Results

The internal consistency of the measures and results present the economic activity in the Maramures County, Romania. The results highlight the extensive structure of the socio-cultural elements and provide a possible indication on how to solve organizational problems and establish a model for future leaders and sustainable leadership. Taking into consideration the traditional model of leader, in the first part of the survey it was possible to identify the personal characteristics of the leader.

The leader profile from Maramures County is a business person aged between 25-40, involved in small and medium family businesses, in order to provide extra money in support of the family.

It was also possible to identify Pavitt's (1981) taxonomy groups and specify that most activity describes the level of technological opportunities in industry, the influence of innovation and new technology for future development, and the harmonization with customer needs.

The results can be divided into the categories of retailer and supplier dominated industries (44.4%), including traditional manufacture sectors, food, textiles, clothing, handmade products (8.8%), training and other services with the involvement of women in the majority of organization typologies (20.8%).

The economy, and production, occupied the fourth place with 59 participants (23.6%) involved, including people from the mechanical industry, electrical and electronically products and furniture.

As the factors proposed are generic in the leadership profile, non-productive activities are also very successful in our region which is a good sign considering that Maramures County was a mining region (after 1989 all the mines producing minerals, coal, and gold were closed) which was declared an disadvantage economical zone. Tourist services, travel agencies and traditional handcrafts and manufacture small business are significant for our region.

This is important because Maramures County is a UNESCO heritage site in terms of its culture and tradition, and hospitality has been an important factor in the development of our region. In fact if we consider that the mines were closed, and the majority of male manual power emigrated to developed countries.

The number of unemployed people from textile and ceramic factories is a significant target for the new model, the majority of these people are involved in businesses as individuals or families and only 49 people belong to partnerships association and private activities (Table 1).

Table 1. Legal Structure of the businesses in Baia Mare city, Romania

		Legal Structure of the business				**Total**
		single	partnership	limited partnership	cooperative	
Gender	M	49	27	18	5	99
	F	68	57	21	5	151
Total		117	84	39	10	250

The leader profile also included the education level of people involved in different business activities. The research used a scale from 1 =general school, 2 =middle school, 3 =high school, 4=professional and art school and, 5 = academic education, which was used to identify the education level of managers who were our target group. In conclusion, educated people are involved in business activities and have the courage to open and manage organizations Table 2. Because production and manufacture are the engine of economy, it is necessary to encourage this segment. Thus production activities also require educated more responsible people who are open to the new changes from global market.

Table 2. Education Level of Romanian business leaders

		Type of Operation					**Total**
		manufacture	retailer	wholesaler	services	5	
Education Level	1.00	1	0	0	0	0	1
	2.00	12	38	3	12	0	65
	3.00	2	8	0	0	0	10

	4.00	6	21	0	6	0	33
	5.00	38	44	19	34	6	141
Total		59	111	22	52	6	250

In part 3 of the survey, the questions established the characteristics of leaders. A PRELIS™ program was used to manipulate, transform, and generate data, compute moment matrices, and perform regression analyses and exploratory factor analyses. To maximize the difference between the 250 respondents and arrange them into different groups in function of leader typology, the following variables were used: age, type of business (services, manufacturing, retailer and wholesaler) and business structure (private, individual or state). Path Analysis is the statistical technique used to examine causal relationships between two or more variables, external factors = EF, decisional factors = DF, affective factors = AF, and internal factors= IF, as variables. The final selection of variables that can influence the leader model is realistic because it is representative for each of the four variables (Table3).

Table 3. Number of Clusters in function of the variables

Cluster	1	87
	2	35
	3	94
	4	34
Valid		250
Missing		0

In terms of the cluster grouping, out of 250 people, 94 belong to cluster 3=affective factors, and 87 to cluster 1= internal factors. In function of age, the younger generation is involved in independent activities, services and wholesale.

4.1. A Leadership equation

Three aspects are common for many leaders: employee, self confidence and objectivity in dealing with others. An equation for the new millennium leadership can have the following ingredients:

$$E^6 = \begin{bmatrix} Energy & Edge \\ Execution & Energizer \\ Economy & Evolution \end{bmatrix} = Q = Quality \qquad [1]$$

To meet the demands of emerging markets, companies are accelerating the development of talent and leadership.

4.1. A proposed model profile of leaders

This paper looks at sustainable leadership in small and medium enterprises in Maramures County, and examines the distinctive challenges encountered by leaders of small organizations in pursuing sustainable leadership.

For a descriptive analysis clusters were created, and the 250 respondents were divided into five different groups concentrated around the same factors of influence. We thus considered: personal information of the individual: age, gender, work experience, and business profile: type of business (services, manufacturer, retailer and wholesaler) and business structure (private, individual or state).

The findings of the survey showed that a big segment in relation to age considered that a leader is influenced by the relation between the leader and the staff (staff – leader). 78 respondents considered that cluster 1 = individual culture (cultural education) is important for a leader as a person influenced by his/her own education, management style, work experience and making his/her own decision.. One of the most important qualities addressed by the research team confirms the extent to which the practices

and values associated with leadership are universal. The participants/leaders were asked to rate the experience along certain dimensions, such as:

- the internal factors leader-staff:
- the perceived reaction between leader and group members;
- their emotional reactions and their feelings towards group members;
- their decision factors regarding group members.

5. Conclusions

The Cross leader model is useful in identifying the abilities, that enable leaders to adapt in different cultures spaces, and as a final conclusion the study presents a model for cross cultural competence for Romanian leaders.

A new cross cultural model also considers the traditional quality indicators: staff, innovation, strategy and behaviour in the financial market, production and technology.

The transmission system does not work sufficiently in Romania, the management of information and communication on the hierarchy pyramid is poor, the information flow does not ensure the understanding of employees' tasks, rights and responsibilities.

The major findings are how cultural similarity is greatest among organizations that constitute a cluster concentrated around the same dimension:

- dimension of cultural values, individual culture and how culture is similar or dissimilar from each other;
- dimension of how peoples' ideas of good leadership vary across culture;
- dimension of changes in culture of communication, role of emotional intelligence;
- dimension of interactive leadership platform.

In conclusion, being aware of the particularities of other cultures and organization management, learning (Fullan, 2015) the differences and assimilating corresponding behaviour are important values, together with

- knowledge of professional information;
- familiarity with the tradition of other cultures, tolerance.

The results show the quality balance of culture with its impact on competence and organization efforts and the feedback balance between economic success and the ability to sustain expenditure.

In an economic crisis and with the fluctuation of employees in organizations, with the free market movement from East to West, the study does not show many significant differences between leaders and staff, the opinions of managers and subordinates in comparison with other countries:

- lower orientation to human relationship, business efficiency, individualism and collectivism;
- higher orientation to autocratic management.

Culture is expressed through people's attitudes and actions because culture also has economic effects and might be moved

- for leaders - their culture reflects a future vision, a portfolio of solutions regarding the construction, objectives of organization;
- for staff / employee - their culture allows them to understand the necessity, utility of objectives as a factor in their accomplishment.

Culture, history, tradition can be evaluated in a similar way. Thus various new elements related to the employees, skills and creativity as well as to the culture where the organization is located are the new direction in organization management.

The east culture contradiction with west culture arose from the specific characteristics of the surveyed organizations in terms of the cultural and historical characteristics of each country. Recent research has focused on the charismatic and transformational theories of leadership and has examined its application in the cross cultural context and the new concept of global etiquette.

The comprehensive model proposed by author will help local organizations and their leaders to understand the current market conditions in the country and outside, the demand for products or services, as well the business culture. However, even the most talented leaders will achieve little if the culture does not allow them to influence people to work toward a common goal.

As the present study was conducted in Romania, further research should be repeated in other countries with similar economic conditions with a non-western culture. This idea echoes calls for a cross cultural, leader model in the field of business.
The present study was the limitation of organization from a specific zone from Transylvania region from Romania. The results of the present study could be used for a future leader model unit.

Limitations of the Model
The study has certain limitations that must be acknowledged, introducing opportunities for future research. First, the scale of measuring the leader profile and shaping his/her leadership capability was developed and tested only with SMEs in Maramures County, as a case study of a disadvantaged area, thus, more studies should be conducted in other industries. Secondly, the individual informants were the managers who completed the questionnaire. Future research should ask more people to complete the questionnaire, for example R&D managers, engineering managers, even employees.
The model developed in this study suggests further research opportunities in this field. Further research could examine the leader's behaviour and the factors that drive or hinder innovation of SMEs and how leadership sustains harmonization with the environment protection standards. Another area of research is to explore the performance of industrial SMEs resulting from leader and leadership sustainable development in terms of their innovation capacity.
The suggested areas for future study could potentially be expanded to identify and investigate sustainable leadership in other countries.

Impact of Land Externalities and Real Estate Economic Potential

Janka Babelova, UCJ LFUK, Comenius University in Bratislava, Sasinkova 4/a, 81108 Bratislava, Slovak Republic, jbabelova@stonline.sk

Abstract

Each land may bring externalities, positive, as well as negative ones. It results from the place where they are located and their previous utilization. Also, the need for change in the soil utilization, which is time and financially demanding, seems to be an externality. The building boom in Slovakia in the recent 15 years has caused several serious problems. Predominantly, it is the origination of negative externalities which endangers the availability of high-class building sites, and they have an impact on their economic characteristics in relation with the uncoordinated build-up of new investment projects. At the same time, they are a limiting factor for the sustainable development of the region. In the paper a model case is presented - from the view of investment interests of development companies - in a very interesting developing region, close the capital city of the Slovak Republic. The aim of the author is to point to the origination of negative externalities, which have a direct impact on the quality of life of inhabitants living in the region, in the frame of its sustainability.

Keywords: Land externalities, Land development, Sustainability

Introduction

In the functioning economy, a well-functioning real estate market has a role which is irreplaceable. A fast development of financial tools in two recent centuries caused that nowadays the real estate market does not represent an independent market, but it is an integrated part of global financial markets. Regarding the fact that the real estate sector is closely related to the functioning of the economy as a whole, whose not proportional development presents no small risks in the development of the financial sector and economy in its entirety. Land, including both terrestrial and marine space, is one of the most important resources in any country, it is a key to economic growth, and it plays a central role in national and community development; the management of land is a critical and essential requirement for sustainable development. Many of the issues that affect land development and management, impact ultimately on economic, financial and environmental sustainability and on the country's social development (Spirkova, 2015). The long-term problem in the Slovak Republic is grabbing of farmland for the purpose of mainly large development - building industrial and residential projects. The Slovak Republic is one of the transition economies, which since 1990 has undergone major political and economic changes. Factors that contributed to the grabbing of land are primarily due to the need for new residential, industrial and commercial sites, as well as transport infrastructure. It is mainly a response to population growth and increased demands on the quality of life and standard of living (larger residential units, more sports activities and social facilities, etc.).

Problem identification

The building boom in the Slovak Republic in the last 15 years has caused several serious problems. It was a consequence of externalities origination (we will discuss externalities later in the text), id est, prevailingly of negative ones as e.g.: concentration of the area, non-solving or just partial of questions of citizen, technical and transport infrastructure from the side of local self-administration, which subsequently caused and causes a big amount of problems for present and future users of real estates, built and traded on the real estate market (Spirkova, 2015). One of the determinants of this stage is the

failure of the state administration to solve developmental activities. They are predominantly building authorities that contribute to the existence of negative externalities because they are under the pressure of rich developers. Externalities present a case of so-called market failure, requiring the correction from the side of the state. According to Spirkova (2015), just externalities significantly influence the economic potential of real estates, as they are also manifested in real estate evaluation. Here the externality is understood as any outer influence, which may positively or negatively influence the price of the real estate, in this case, we speak about economic devaluation. As an externality might seem also so-called effective age, which is used, when the real estate is in a bad condition in comparison with its real age. This implies that an effective age is on a large scale of subjective indicators, and it might be misused and overvalued the value of a real estate in its actual condition.
The externality is an impact of human activity on the welfare of others, who are not involved in the mentioned activity. In the case of unwanted impact, it is a negative externality (they prevail in the field of the environment), in the case of favourable impact, it is a positive externality. If the externality is present, the market does not allocate sources effectively, because a producer of an estate does not count in the value of the externality into the production. So the scope of production is higher and prices lower than social expenses. The social profit is not maximized in the point of balance between offer and demand, as it would be under normal conditions in fully functioning markets.

Externalities and their impact on the territorial development V4 countries

In terms of sustainable development in the urban development, the important role is played by housing as a basic component of the urban environment and social development. The statistics show that:

- 68% of the population of EU countries live in urban areas,
- 85% of EU GDP is generated in cities,
- urbanized areas represent about 70% of the total primary energy demand,
- energy consumption in urban areas is growing annually by 1.9% (compared to 1.6% globally),
- municipalities are part of the problem but also part of the solution.

According to the reference scenario of the International Energy Agency, "urban" energy consumption will grow twice as fast compared to the EU as a whole. Cities and regions have great potential for the realization of energy efficiency measures and using renewable energy sources with a positive impact on the local economy, employment, investment, and innovation.
All V4 countries - Slovakia, Czech republic, Poland, and Hungary - (at differentiated rates) confront negative effects due to trade liberalization, income disparities and the development of the well-paid social class, as well as the growing number of cars during the transformation of urbanization development. This effect is most visible in the metropolitan areas of major cities (Budapest, Warsaw, Prague, and Bratislava). The same trend occurred in the case of other major cities. At present, the suburbanization tendencies are constantly getting stronger. They are related to the migration of urban population to the surrounding "green" zones in the nineties of the 20th century. Installation of a so far free country still brings negative consequences. It creates inefficient and unregulated structures (sprawl) of land use, which will for a long time obstruct sustainable urban development (Gremlica, 2002).
The uncontrolled spread of cities into the country, manifesting in all V4 countries, is disorganized and uncontrolled by definition. The situation is additionally complicated by the fact that land use planning have relatively weak instruments. Corrupt behaviour is evident at the local level at issuing permits and making a decision throughout the whole Visegrad region. Supported are investments in developing on new "green field" and large devastated or otherwise unused areas (brownfields) remain unnoticed. As a result, the built-up area extends about 1% per year, with a serious impact on local hydrological cycles, the structure of the country, local climate, landscape, biological or cultural diversity and many other things.
From the economic, social and environmental point of view, we can characterize "sprawl" (spread build-up in the countryside) as an undesirable form of suburbanization (Ourednicek, M. 2002). It is the uncontrolled and unconsidered placement of residential or commercial real estate in the country, which is typical of Visegrad Countries. The result is usually mosaic structure in newly developing urban areas.

The main force of such development are efforts of individual landowners or developers to maximize their profits. Locations which are marked by sprawl, increase of economic costs and reduce the quality of life in the suburb. It is mainly caused by lack of territory connection, lack of roads and sidewalks, garbage collection, maintenance in winter, introduction and management of technical, social and transport infrastructure, and extreme dependence on the personal automobile.

From a sustainable development perspective, it is desirable to monitor the economic value of long-term perspectives and keep in mind that the values in relation to the territory have spatial dimension and the events which are taking place in different areas are interdependent but mutually influencing. This means that the values and events in the area have an external effect - to act as externalities for other territories.

With regard to economic aspects of the built-up area, we must also talk about the cases of so-called market failure - externalities which require correction by the state. Economic theory distinguishes positive externalities (increasing value of the territory) and negative externalities (depreciation of area, depreciation of housing in part of the city).

A positive externality occurs at the moment when a subject obtains benefits from the action of others without paying for it, respectively to have an appropriate share of (in proportion to its benefit) the costs. Because of that comes to post-production of given estate and optimal level of output is not achieved socially (Stefunko, 2005). Therefore, the State must ensure the contribution (payment) of these provisions to externalities providers. This theory, according to the Austrian school totally ignores the fundamental centre of the functioning of the real economy (market). Real life is, in fact, full of positive externalities. In fact, we can hardly find any human action that does not cause positive externalities to "neutral" (not cost carrying) person. For example, if a Volkswagen decides to build large factories in a region and thanks to that the real estate prices in this area arise, it represents the positive externality of real estate owners. Does that mean that we should now be forced to pay some contribution to Volkswagen? If yes, how? We have previously emphasized that preferences can be demonstrated only by the specific procedure. If the automaker decides to build a given factory, it does it because it (ex-ante) expects from that step more income than the costs that are associated with it. It does it without consideration of any possible cash support from property owners. On the other hand, if the automaker is willing to implement the project only with a certain minimum monetary support from property owners, it may let them know. In case that property owners are willing to provide given amount - they will demonstrate that the benefit of the project is higher than the cost associated with it, so the given amount is provided. On the other hand, if they will not provide the given amount, the costs exceed the potential benefit. Again, we obtain the conclusion that only with a free interaction between market participants we can come to the optimal level of output and the fair distribution of costs and benefits associated with it (Mises, 1992).

In general, we can say that positive externalities are caused by decisions of an individual or company, but no individual or firm does obtain the full benefit from their decision. Benefit acquired by a company or individual because of their decision is smaller than the benefit the society gets from it. Negative externalities occur when an individual or company makes a decision for which do not take the responsibility and cost of such decision is a burden for society. Positive externalities include better environment, increase in value, and thus also house prices and rents, population dispersal, reducing the concentration and movement of construction from the crowded centres, improving health and hygiene.

A negative externality is a condition where the conduct of one or more entities formed a harm to (cost) uninvolved (of income) side. Therefore, the state must intervene and stop this kind of action or, at least, minimize it. Such a situation can certainly occur, and it is happening in the real world. This situation does not constitute a market failure, but the failure of the state which is unable to protect private property. But for example, if some plant with its activities pollutes a river, it cannot be viewed as a market failure. The problem is just at that point that in the fact there is no present market. In the market conditions, the river owner can demand from the polluter a full compensation for damages, including lost profits, which were caused by pollution. In contrast, in the current system, the river is owned by the state. And the state, instead of this approach, selects either the (small) fine and / or completely disable a given activity.

In any case, there is an inefficient and unfair solution that leads either to an unreasonably (having regard to all the real costs) high level of activity, or too small or none. Conversely, the free market through the interaction between (potential) victims and (potential) damage makers leads to an optimum level of

troubled operations. Thus, a solution does not lie in state intervention, but in the full state disestablishment of all rare resources and consequently to the absolute protection and respect for property rights (Rothbard, 1997).

Negative externalities can be noise and air pollution during construction, the decline in real estate prices, various additional requirements directed at the government, the failure of governments to manage land use plan and activities of building authorities, developer aggression, concentration of construction and many others, which can result in a variety of extreme situations such may be the abdication of city due to aggressive and unfair actions of developers to push out their requirements.

As an interesting example, we can mention the UK from the period of the great industrial revolution in the years 1750-1850. The population in this period increased by almost 190%. Increased urbanization and cities have developed with rapid pace, where bureaucratically centrally enforced land-use plans did not exist. Landowners, developers, and small builders coordinated their activities in order to meet needs of different market segments while favouring contractual limitations. In practice, this meant that if the land or any rights connected to is were transferred to another entity, the transfer, whether it was a sale or lease, usually contained several specific conditions or contractual constraints that legally bind each party in a way that breaking of the terms could make an agreement invalid. They controlled and thus restricted the form of exploitation of land or property built on it. There were also applied some contractual obligations, which determined the type of building or even use each constructed buildings. The most common are those that prohibit certain types of business or activities. Even today, many obligations in Britain are valid, and some buyers are confused about the restrictions of type "prohibition of breeding pigs", "prohibition of the manufacture of soap" or "prohibition of creating a bad reputation of the house". Many activities were banned because of these restrictions, such as those that produce waste or noise. By this, the owners could define the admissibility of certain activities. So, in industrial zones, owners could control the character and size of the factory. Contractual obligations, therefore, were able effectively to counteract the negative externalities, and can be established for a fixed period or for a timeshare property lease and in rare cases, even for an indefinite period of time (Ivanicka, Spirkova, 2013).

Among the important externalities that affect the price of the property including crowding, which increases demands on transport, construction that makes the life unpleasant during construction, requirements for parking spaces, reducing of green areas for relaxing and many others, and acts as a negative externality, although for a small number of the population in the new site it can be positive, as it reduces commuting trip to work. If the authorities allow crowding, they cause a deterioration of the living conditions of the natives while reducing the cost of property which will be less desirable than in the original building site.

The excessive intensity of use of the built-up area. We record it particularly in the attractive majority of towns and cities mainly in their centres, where inside-block spaces are built up, there is an effort to raise the level of new buildings. The result is a deterioration of microclimate, increase of dust, very dry air or overheating of the city in summer. Also, there may be clogging of drains during torrential rains, like water on "hard" surfaces of roofs, paved courtyards, and parking lots have nowhere to drain.

Increasing the number of users of such urban areas is further aggravating the traffic situation and problem with parking are growing. Last but not least, there is often damage to the aesthetic quality of the place. Secondarily, the deterioration of attractiveness of the territory may occur, which was the primary cause of area overexploitation. Often referred to a sustainable alternative to excessive concentration in the centres of the polycentric development, i.e. development in other centres that attract investors and visitors.

The decline of the use of the built-up area is the opposite of the previous two different effects, whose common feature was the disproportionate growth (extensive or intensive). The inadequate or insufficient use of area may occur locally but can also affect entire cities and regions. The primary cause is a loss of attractiveness of the area, which causes that residents and businesses are leaving for the other attractive destinations. On their place may at first come members of lower social strata and less successful companies, but gradually also more successful of them go somewhere else. Reducing social status of the territory accompanied by other adverse effects for its sustainable development: deteriorating of age structure of the population, increase in the turnover of users (growing share of temporary use), decrease of the number of customers and reduction of their purchase power leads to the closing of shops, service

establishments and educational institutions, the maintenance of buildings and public spaces impairs. A typical environment where these phenomena occur is the rural area away from larger centres, as well as downtown and older neighbourhoods of some cities.
Excessive functional specialization and concentration - one-sided development of only one function, for example, the concentration of office workplaces, shops, and leisure and entertainment activities. The following are typical examples of disproportionate functional specialization in the area:
Imbalance of residential and workplace functions in the territory, thus separating living space from offices or industry, entails high costs for transport between residence and workplace. This transport also burdensome the environment.
Extensive area build-up - suburbanization, urban sprawl. In the last fifteen years, we are witnessing a large increase in residential areas or office areas "greenfield" facilities in large cities. Suburbanization and urban sprawl consume parts of the country, which could be used for example as agricultural land or forest. That is how natural environment disappears and loses its ecological function. Extensive built-up areas can cause a change of microclimates, require connection to utility and transportation networks caused by operating costs of this infrastructure and last but not least, change the character of the country, usually for the worse. Sustainable alternatives for the country's extensive build-up is the better use of built-up areas, particularly with the use of land which has lost its original use, such as abandonment or underutilized manufacturing and military sites, etc (Maier et al., 2012).
Urban sprawl. In many developing countries, urban sprawl comprises two main, contrasting types of development in the same city: one is characterized by large peri-urban areas with informal and illegal patterns of land use. This is combined with a lack of infrastructure, public facilities, and basic services, and often is accompanied by little or no public transport and by inadequate access roads. The other is a form of “suburban sprawl” in which residential zones for high- and middle-income groups and highly-valued commercial and retail complexes are well-connected by an individual rather than public transport. Urban sprawl adds to the urban divide, pushing social segregation along economic lines that result in a spatial difference in wealth and quality of life across various parts of cities and metropolitan areas run down inner cities and more suburbs. Suburbanization in developing countries happens mainly because people – rich and poor – flee poor governance, lack of planning and poor access to amenities. "Sprawl is a symptom of a divided city” (Unhabitat report, 2010). Urban sprawl has a negative impact on infrastructure and the sustainability of cities. In most cases, sprawl translates to an increase in the cost of transport, public infrastructure and of residential and commercial development. Moreover, sprawling metropolitan areas require more energy, metal, concrete and asphalt than do compact cities because homes, offices, and utilities are set farther apart.
Status, where the property rights are in the locality, may also become a positive or negative externality. If for example, grazing or other valuable sources are common ownership, nobody takes into account the costs associated with such property. Defining and encouragement of private property rights is often an effective way of addressing how to manage ownership of valuable resources. Not surprisingly, the most economically developed countries have highly developed institutions dealing with private property.
Advanced economies, which have traditionally well-functioning institutional environment which is generating implicit rules, governing jointly owned resources and thus have an impact on the cost of managing them. On the other hand, such an approach is not effective in emerging economies because it causes that the property, which is mutual, is often handled as it does not belong to anyone.

Methodology

The combination of several scientific methods and approaches (analysis, abstraction, synthesis, induction, deduction, comparison) were used for the elaboration of the issues in the paper. The important sources of data were scientific literature devoted to this issues and research report Unhabitat of the Ministry of Economics SR, a database of the Slovak statistical office, the Land Register Office SR, the Office of the Government as well as international institutions. Another knowledge was gained in personal consultations and by the method of brainstorming with professionals and scientific workers in the field of territorial and spatial planning and the real estate market from Slovakia, the Czech Republic, Austria and Great Britain.

Consequences of negative externalities at uncontrolled building activities are presented in the model case of the municipality Chorvatsky Grob which is an important satellite at the capital city of the Slovak Republic - Bratislava.

Model case

The municipality Chorvatsky Grob between the municipalities Ivanka pri Dunaji, Bernolakovo, Velky Biel, Slovensky Grob, and the capital city Bratislava. It is approximately 15 km far from Bratislava. At present approximately 7,000 inhabitants live in the village, out of them, just 4,800 have the permanent address there, with the outlook for 20 years according to the territorial plan approximately 60,000 inhabitants are estimated. The village has a well-built information system, active approach to implementation of innovation and has an approved territorial plan.
Construction boom in this village started approximately in 1998, when reforms in the area of housing policy in Slovakia allowed implementation of several new forms of housing financing in retail as well as corporate area and so to increase housing availability for inhabitants (e.g. project financing, lease of real estates, pre-mortgage and mortgage financing and also new forms of building loans for natural entities - citizens). Improvement in the market environment in Slovakia also manifested in the intensity of residential housing in attractive locations close to Bratislava, as which the territory of Chorvatsky Grob is also considered. The period 2003 - 2010 meant for the municipality an extensive development, which presents almost 6-time increase compared with the original build-up area. The mentioned situation, according to experts, might be compared with the development of Chilean towns, which means, that the original village with 1,200 inhabitants today has 6,500 - 7,000 inhabitants. This huge increase in inhabitants was caused predominately by the construction of residential zones in the way of non-professional and non-conception constructions and not coordinated approval process. According to the opinions of professionals, this benevolence in permissions for construction of large housing zones does not have anything in common with the complex urbanization, the logic of housing environment and be no means with the public interest of the village and its inhabitants - present, but also future ones. The mentioned situation causes a devastation process, which at present the authorities of municipality and construction administration try to stop, it means to stabilize and partially correct past controversial decisions. But it meets with the barrier of contradictory and negative standpoints of appeal organs in the state administration.

Result and Discussion

In case “Chorvatsky Grob”, we may talk about a significant negative externality as the village is facing a possible collapse due to subsequent reasons:

- unsolved questions of technical, transport and citizen infrastructure (e.g. missing new elementary school due to a big increase of young families, health centre, post office and so on),
- the unsolved question of realization of housing environment (the square, sports zone, greenery and so on),
- uncontrolled concentration and an unsolved technical and transport infrastructure (which causes a huge traffic jam when commuting to work in the morning and in the evening - car colonies are long even more than 5 km and to travel 15 km from Bratislava lasts even more than 90 minutes),
- there is not created the possibility of optical internet connection in all streets - many streets do not even have fixed phone lines,
- minimum shops (e.g. just one Tesco express store, pharmacy, drugstore and few cafes and so on),
- the risk of possible future serious demographic and social problems and so on.

Factors, which significantly influence and will influence the current situation we may characterize as follows:

- the pressure of developers as well as individual subjects to widen residential constructions, which causes insolvable problems with endangering of already existing housing (see Fig. 1),

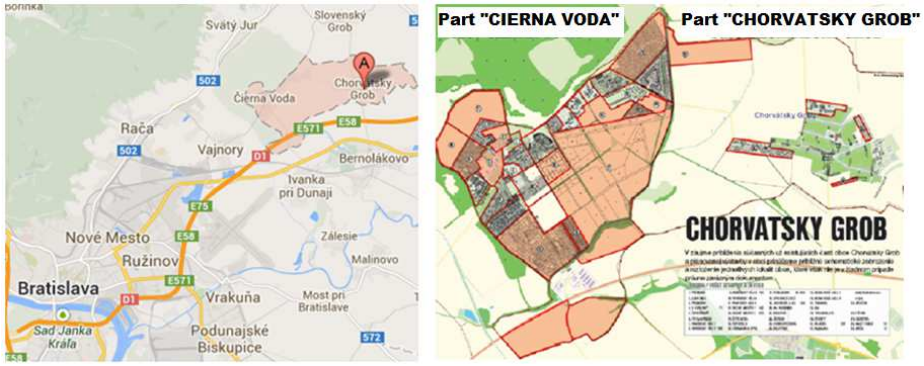

Fig. 1 Location of the planned new building activities in Chorvatsky Grob – part Cierna Voda
Source: elaborated according to the data from the territorial plan of the municipality

- negative approach of organs of the state administration in the form of their standpoints to the current situation,
- inflexible - in some cases even limiting legislative (inferiority of the system of state administration and economic policy) for the management of self-administration,
- conflicts with the municipal authorities, which does not create the space for realization of changes and further development of the village due to conflicts between the old and new part of the village (the old part of the village has despite a significantly smaller number of inhabitants. But in the municipal authorities it has approximately the same number of deputies, who slow the support of development projects in the new part of the village) and so on.

Another negative externality, which significantly influences the quality of life of inhabitants of the village is repeated closing of so-called “Triblavinska road” by a private, public limited corporation (see Fig. 2).

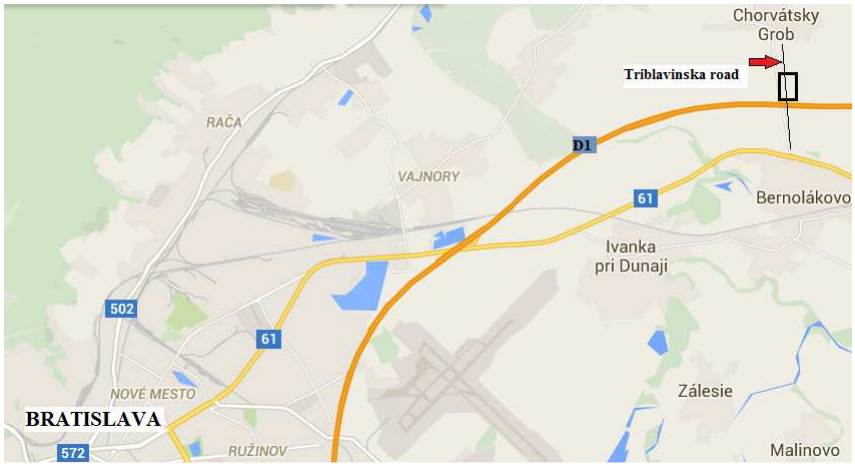

Fig. 2 The part of Triblavinska road repeatedly closed by a private company, which cuts connection to Senecka road in direction to the capital city Bratislava
Source: own elaboration of the municipality map - Chorvatsky Grob

The importance of this road is in the fact that it links a part of the village Chorvatsky Grob - Cierna Voda with the village Ivanka pri Dunaji and with the old Senecka road. The acting of the private company is in conflict with public interest. It is necessary to say, that in the wording of the Road Code about the special purpose communications, the municipality performs the state expert supervisory. In the wording of § 3c sec. 2 of The Road Code as the organ of the state expert supervision the village cares for provision of land road and supervises if the duties, the conditions of land road usage appointed by the Road Code, and the regulations issued for their execution are kept, as well as regulations of the road administrative organs.

Conclusion

As the model case showed, negative externalities may have fatal consequences for the regional development in the view of the improper realization of developing projects, which is mainly related to pressure activities of development companies to gain the highest possible profit. This situation is also caused by uncontrolled concentration, and unsolved questions of technical and transport infrastructure, which we consider as badly managed development and bad regulation of building activities by the organs of the state administration. Such approach may even result in an abdication of representatives of municipal bodies. The most important negative externality of the real estate market in the Slovak Republic is the fact, that there is no institution that would deal with complex characteristics of real estates and allow an easier orientation in the market for the buyers. Real estate companies have in their offer just a small amount of real estates and their priority interest is to obtain a commission and not to provide complex information for a client about positive and negative characteristics of a real estate, including building sites.

Abstract

Geographic and climatic conditions in the Danube Delta have favored the development of major renewable natural resources: fish, reeds, meadows, forests, medicinal plants, mushrooms, etc., which are capitalized through traditional economic activities of the local population. A resource is an important natural delta landscape with particularly attractive characteristics. The landscape is valued by tourism activities, both by specialized companies and the local population. In this study, we wanted to analyze the involvement of local government in the Danube Delta, in order to identify solutions to increase the living standards of people in this area. To do this, we applied a questionnaire to 21 representatives of local governments, depending on the number of inhabitants that it has common. In interpreting the results, we used: the test of association (chi-square); Critical value (Pearson's C) and the critical value (Cramer's V).

Keywords: standardized residue, tourist movement, probability, questionnaire, test of association, association test (Chi-square), respondents

Introduction

Danube Delta Biosphere Reserve (ARBDD), delimited by law, has a total area of about 580,000 hectares and is located in southeastern Romania. DDBCA are 25 settlements, organized in 7 villages, located entirely in this area: (Ceatalchioi, Pardina, Maliuc, Crişan, C.A. Rosetti, St. George, Chilia Veche) and Sulina. There are also common areas were partially DDBCA (Nufăru Beştepe, Murighiol) and suburban Tudor Vladimirescu Tulcea Municipality (*** Zonal Spatial Plan Delta, 2015).
Local government plays an important role in determining and understanding the importance of the Danube Delta Reservation, especially the tourism potential that it has for its residents this area and what to do to correct this situation (Palmer A., 1994).
Rural tourism and agritourism activities are intertwined, complement and reinforce each other, forming an area to be organized specifically taking account of the specific geographical, economic, social, etc., the specificity of its products and the role they have to play in rural development (Alecu Ioan Niculae, Constantin Marian, 2006).
Europe compared to other regions in the world has a very favorable position where you can find most industrialized countries possessing an impressive tourism potential natural (characterized by exceptional landscape) and anthropogenic (represented by historical, cultural, art and architecture) (Albu L., Dobrescu E., 2005).
To encourage rural tourism in the European Union, we have developed a number of programs. They noted the following programs: "Expert", "The Village I Love", "Data Base on Rural Tourism Services",

"Interregional Cooperation Celtic", "European Rural Tourism Network", "Transnational Agri -Tourism Information Centre", " Study on Rural Tourism ", and so on. a. in some of them it was involved and Romania (Kotler Philip, Gary Armstrong, John Saunders, Veronica Wong,1998).

The research method

As a research method we used questionnaire method and interpretation of the results we used: the test of association (chi-square), the critical value, the value of Pearson's C and value Cramer's V (Merce, E., ş. a., 2010).
The questionnaire was applied to local governments within the Danube Delta, it was distributed to 21 local government representatives, depending on the number of people you have common (less than 500 inhabitants, between 501-1500 people, 1501 - 3,000 inhabitants), the surface that extends commune (1,000 ha, 1001-5000 ha, 5001-10000 hectares and over 10,001 ha), but also by the industry mainly households in the commune represented (fishing, tourism and agrotourism , agriculture or other concerns).

Results and Discussions

Analyzing the structure of the number of inhabitants according to the area, we note that most common of those studied have less than 500 inhabitants and a surface area ranging between 1,001 and 5,000 ha. Also, localities have less than 500 inhabitants represent 62% of those studied, followed at a great distance from villages with 501-1500 people (24%), respectively municipalities with 1501-3000 residents (14%) (Table 1.).

Table 1. Structure of inhabitants according to the areas that stretch the villages

On what surface spreads town you represent? (ha)					
Number of inhabitants	**<1,000 ha**	**1,001 – 5,000 ha**	**5,001 – 10,000 ha**	**> 10,001 ha**	**Total**
< 500 inhabitants	19.05%	28.57%	14.29%	0.00%	61.90%
501 – 1,500 inhabitants	4.76%	4.76%	9.52%	4.76%	23.81%
1,501 – 3,000 inhabitants	0.00%	4.76%	0.00%	9.52%	14.29%
Total	**23.81%**	**38.10%**	**23.81%**	**14.29%**	**100.00%**

(Source: Data processing from the questionnaire)

Regarding areas analyzed municipalities, most of them falls among those who have an area of 1001-5000 ha. The under 1,000 hectares and 5001-10000 represent a similar share of 22%, and last fall the more than 10,000 hectares (14.29%) (Table 1).
Between representatives of local governments who answered the questionnaire, most said that the main occupation of the inhabitants is agriculture (38%), followed by fishing (24%), tourism and rural tourism (19%), and that other concerns, in an amount of 19% (Table 2).

Table 2. Structure of the inhabitants number according to the most prevalent activities of the population

In which field is occupied most of the population?					
Number of inhabitants	**agriculture**	**other concerns**	**fishing**	**tourism and agrotourism**	**Total**
< 500 inhabitants	23.81%	9.52%	19.05%	9.52%	61.90%
501 – 1,500 inhabitants	9.52%	4.76%	0.00%	9.52%	23.81%
1,501 – 3,000 inhabitants	4.76%	4.76%	4.76%	0.00%	14.29%
Total	**38.10%**	**19.05%**	**23.81%**	**19.05%**	**100.00%**

(Source: Data processing from the questionnaire)

Referring to areas that stretch municipalities analyzed by field of activity, we note that the settlements of the area to 1,000 ha focuses on activities aimed at fishing or other concerns (10%) and those with surfaces between 1,001 and 5,000 ha, activity predominant - agriculture (19%).

Table 3. Surface structure that stretch the analyzed villages according to the activity what drives most of the resident population

In which field is occupied most of the population?					
Surface (ha)	**agriculture**	**other concerns**	**fishing**	**tourism and agrotourism**	**Total**
< 1,000 ha	0.00%	9.52%	9.52%	4.76%	23.81%
1,001 – 5,000 ha	19.05%	4.76%	4.76%	9.52%	38.10%
5,001 – 10,000 ha	9.52%	4.76%	4.76%	4.76%	23.81%
> 1,0001 ha	9.52%	0.00%	4.76%	0.00%	14.29%

In the case of localities with between 5,001 and 10,000 surface and those with more than 10,000 hectares held predominant activity is agriculture, accounting for 10% of communes analyzed (Table 3).
Of the total respondents, 86% of representatives of local government believes that the diversification of activities by people can help raise living standards, while only 14% consider that this is not enough for raising living standards (Table 4).

Also by interpreting Pearson's C respectively Cramer's V, in this case it can be said that developed between the local government representatives and concerns of the inhabitants of the localities surveyed (Pearson's C = 0.51 Cramer's V = 0.66), there Association between the aspects considered, government representatives opinion is influenced by concerns residents of cities analyzed (Table 12).

Conclusions

By applying this questionnaire representatives of local government, the number of 21 localities were classified according to the number of inhabitants according to the area that has the town, but also by the activity of the population in areas analyzed, we have seen a number of relevant factors for the development of this region of the Danube Delta Reservation.

Local administration representatives overwhelmingly believe in diversification activities that can contribute to raising the living standard of the locality represented. Unfortunately they are not aware of programs that can access European funds, most likely lack of interest, especially the poor promotion and distribution of information required by the central bodies responsible for this.

If they could access European funds, most of them would direct money towards the construction / modernization of road infrastructure and the purchase of passenger ships.

Representatives of local governments in most states that in the areas they represent are found in 10 units agro authorized. The same majority share is encountered if unauthorized boarding.

In the next period they are considering investments aimed mainly (57%) modernization of infrastructure (roads and utilities), the investment that they think is most needed in the area to facilitate the increasing number of tourists.

Abstract

In this paper the model for the virtual CAD system measurement engine is introduced. Next, in the kinematics module a few simulation procedures were prepared, which enabled to present the parameters of the virtual measurement machine to serve for higher education field.

Keywords: virtual reality, coordinate measuring, CMM, CAD

1. Introduction

Coordinates type of measurement technique is one of the most important and intensively developed area of a contemporary metrology, which gives a possibility to be integrated with CAD/CAM systems as well as to be implicated in the computer analysis and automatic storage of the measurement data. This made it develop dynamically, however, not many students are familiar with it.

This is a technique which uses coordinates measurement type of machines enabling a full operational control in real time because there is no need for the change of the measurement probe (one measurement process facilitates the measurement points to be determined including discrepancies and the measurement of small and big elements of a complex geometry). Because of that these machines are used in aviation, motor car, machine production and even medical and catering industry.

In the first part of this paper the model of virtual measurement machine is discussed as well as the machine operating process.

In the second part the model of the virtual machine is introduced including some stimulations on the example of the measurement of a given 3D model.

2. Production engineering and the coordinates application technique of measurement

Coordinates type of measurement application technique is different from a standard method of measurement (Bosh, 1995, Estler 1996, Ratajczyk 2005). It is based on the technique where the measurement points are determined in relation to a certain space allocation of coordinates (spherical, cartesian or cylindrical) These points are determined during the process of measurement mostly using the contact surface of the object being measured with the spherical tip of the measurement probe.
There are two types of measurement (Ratajczyk 2005):

- Point type of measurement so called sampling due to the type of the model being proceeded, which this paper mostly refers to.
- Continuous measurement so called scanning.

Having done a certain correction the measurement points can be observed in form of the coordinates of the inner tip of the spherical probe, fig.1.

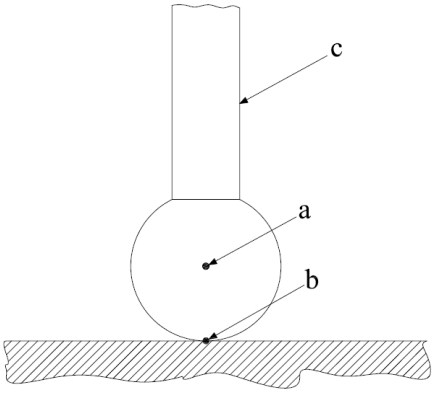

Fig.1. Graphical display of the tip of the probe with the object being measured: a- measurement point as observed, b: measurement point being corrected and a real contact point, c; measurement probe

Coordinate measurement strategy enables us to have high precision results in the time which is adjusted to the production process while the information data is being processed by the computer system (Ratajczyk 2005).

Thanks to the retrieved information the coordinates of the associated object are determined - the process is called *associated geometrical feature* , and is composed of the element being measured. Thus the computer program collects data and makes the calculations on the base of which it is possible to determine the accuracy of the measurement and the geometrical discrepancies of the object in relation to the standards included in the technical documentation.

The basic tool in the coordinate type of measurement is a coordinate measuring machine CCM. This device has mobile elements that move diagonally in three directions

The directions of the movements for these elements are determined by the axis of the coordinates (X_m, Y_m, Z_m) in this way the record is collected as far as the space location of the coordinates is concerned. The information about the movements of the machine elements along the axis is sent to the computer system and the electronic devices being determined by the appropriate formulas (Ratajczyk 2005).

It is very useful that by using this method the measurement procedures can be carried out with the object being in different positions, however it is recommended that the number of measuring points is higher than the minimal number of points for a given measurement proceeding. It is also recommended that the number of points should increase with the increase in the size of the sample measuring of the surface. It is very important when the accuracy of the measurement is to be achieved. The higher number of points than the minimal measurement standard is essential because it is conditioned by the algorithms being used. In addition when the choice of the measuring points is made it is also crucial to pay attention to their lay out, which must be balanced that is meeting the requirements such as; proximity, measuring points spacing and so on (Hocken 2011, Jakubiec 2004, Ratajczyk 2005).

In most cases, only proceeding the elements and the geometrical figures is not enough to determine the measurement of the object. In many cases a direct measurement done in the technical documentation is simply impossible that is why in the coordinate type of measurement both the technical documentation and the real object is taken into consideration. This creates a relation between the distances and angles. Each coordinates type of machine is connected to the computer system the programs of which calculates the values of these relations using the appropriate procedures.

The relations are as follows:

- distance between points e.g. between the centers of the spheres in space, fig. 2,
- the distance between the point and the axis or the surface, fig. 3.
- the angle between the axis, fig. 4,
- the angle between the surfaces, fig. 5.

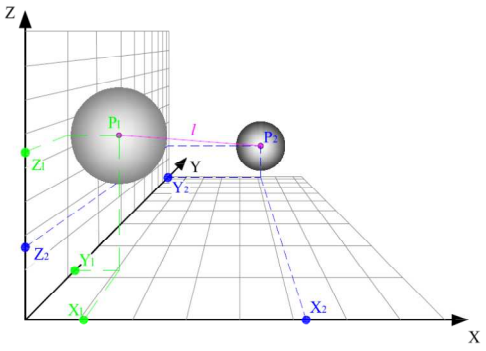

Fig.2. The distance l between the spheres centers (P1 i P2) in space

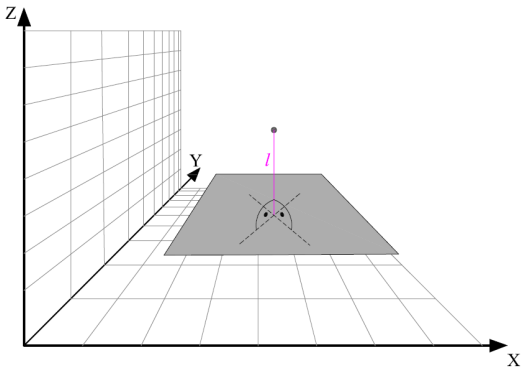

Fig. 3. Distance l between the point and the surface

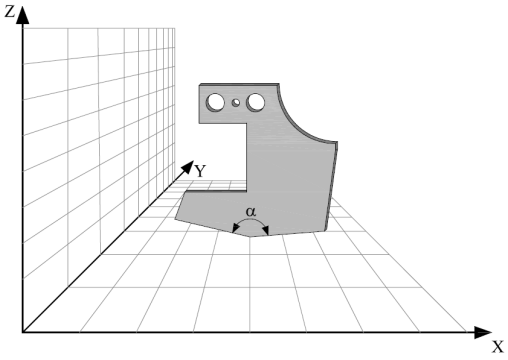

Fig. 4. Angle α between the two sides of the object

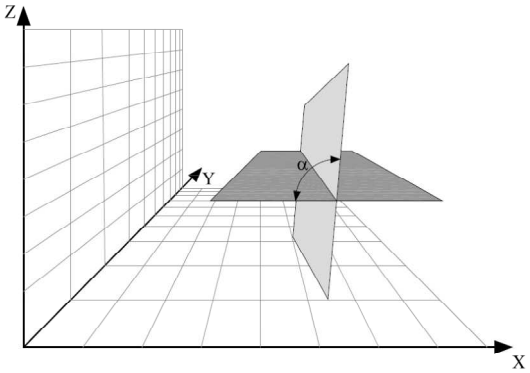

Fig. 5. Determining the angle α between two planes

The theoretical elements of the objects such as; the relation between the elements are determined using the calculations which are based on the pre defined parameters of the very object. These are certain constructions and reshaping enabling to determine the size the measurement of which is impossible to be carried out directly.

2.1. CNC measuring process programming

The proceedings for CNC measurement can be programmed by using 3 methods. The first method is so called *learning programming* where the measurement is performed in a manual mode. The machine saves every operation in its memory and converts them into a CNC programming language. It is important though for the operator to add the secondary points to the program memory, which determines the path of the machine movements.

Another way to carry out the measurement is so called *off-line programming* that is the programming without the machine being used. This program is made by using a special software that takes measurement based on the technical documentation. The whole process can be completed long before the actual production of an item starts. Modern programs enable us to simulate the process which gives a possibility to bring about some changes in case some errors appear (Bosh 1995).

The third way is also called *off-line programming* but it is based on the application of the CAD/CAM systems. This techniques allows for the process being generated in CAD/CAM system where the following operations are to be considered (Jakubiec 2004):

- pivot point system unit (using system reference libraries),
- object positioning (virtual project) on a measurement table,
- the movement programming by selecting the sample points, medium points, defining the depth of the pivot insertion, height of the retraction and the tolerance specifications. In this process the macro-construction is used which makes the measurement process much shorter and thanks to a transparent graphical visualization great many mistakes can be avoided as well.

The system makes it possible to simulate and analyze the program and in cases of any errors the correction can be made very quickly.

3. The concept of the measuring machine model set up

After the analysis had been made as far as the various design solutions were concerned the solution for a simple 3D printer was selected in conjunction with the application of standard printers available on the market. These modules are often used to build Cartesian robots.
The typical 3D "bridge" CMM is composed of three axes, X, Y and Z. These axes are orthogonal to each other in a typical three-dimensional coordinate system. Each axis has a scale system that indicates the location of that axis. The machine reads the input from the touch probe, as directed by the operator or programmer. The machine then uses the X,Y,Z coordinates of each of these points to determine size and position with micrometer precision typically.

A coordinate measuring machine (CMM) is also a device used in manufacturing and assembly processes to test a part or assembly against the design intent.

In order to increase the virtual model measurement capability the HH-A-M7.5 head, made by Hexagon Metrology, was selected. This solution enables us to generate more simulations and at the same time to increase the educational potential of the machine to be used in the future. Building this 3D model the technology of sequence assembly was used [Sąsiadek 2015, Shi-Jei 2013).

The virtual model of the measurement machine is composed of the linear modules Y (1), X (2) and Z (3), the set of measuring heads, (4), bridge, (5) and the measurement table (6) as seen in fig. 6

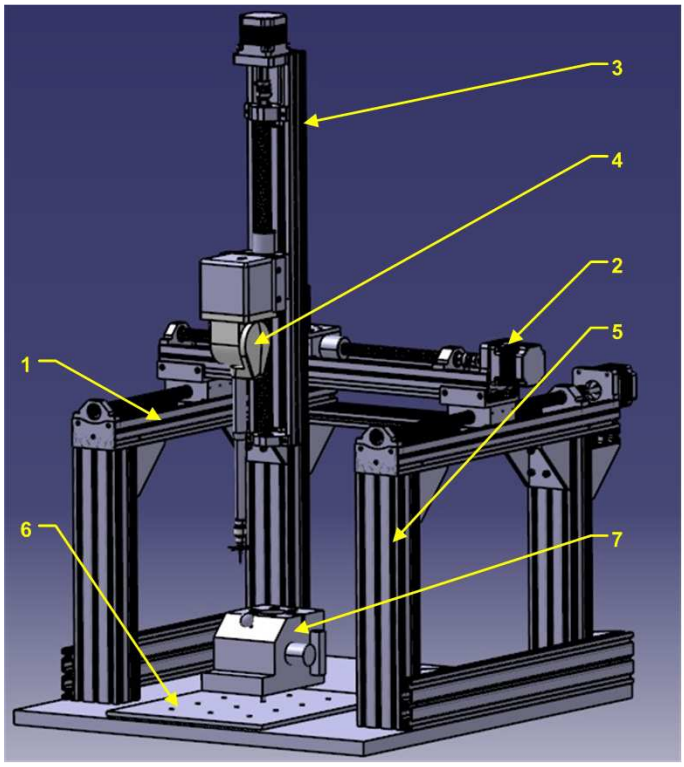
The size of the object was selected so that the machine could perform a sample measurement procedures

3.1. Measurement procedures simulation

The measurement procedures simulation was prepared using a Digital mock up kinematics module of the Catia V5 program. This module is not used for preparing the measuring procedures but for kinematic model verification, which means that every movement of the machine is conditioned by the values determined by the programmer. The movement range of the machine depends mainly on the construction and the solutions designed for a given element.

In order to prepare an educational measuring procedures some characteristic points of the model were selected and measured.

Next, the paths for the pivot run up were defined so that every movement could be as close to the movement of a actual measuring probe as possible. Having determined the measuring points, that is; the ultimate positions of the probe for the medium points determining the idle movement, the simulation was made. Each step of the simulation makes a path from one point to another where the starting and finishing points made always the starting point for the measuring probe (star type of the lower tip of the probe). This tip of the probe determines the starting point for the whole set of coordinates and was placed with the minimal deviation from every axis of the machine (Y=0, X=0, Z=0).



VCMM components:

1. *Y axis module,*
2. *X axis module,*
3. *Z axis module,*
4. *measuring heads unit,*
5. *bridge,*
6. *measurement tale,*
7. *object*

Fig.6. Model for the coordinates type of measuring machine

These are the following examples of the simulation (see table.1) , where :

- **start** - This is the point where the tip of the probe is placed at the beginning of the simulation.
- **approach** - this is the first step which determines an idle movement so as to make a contact of the probe with the measuring point - just before the measurement is actually made. In case when the probe cannot get closer to the point without collision another approach is performed but when the tip of the probe is close enough to the measuring point then this step is omitted. (e.g. in case of close proximity of the measuring points)
- **measurement** - this step is aimed at the target measuring point where the coordinates of the measuring point determine the contact of the probe with the object
- **retraction** - this step is opposite to the approach. The aim of this step is to remove the tip of the probe right after the measurement has been made. Like in the case of the approach when the probe cannot proceed in a straight line without collision another retraction is performed. During the proceeding of this sample procedure eight characteristic points were measured (see Fig. 7).

Table. 1. Stages of a sample measurement procedure (along with coordinates of the target points)

Steps	Points coordinates values		
	Y	X	Z
Start	0	0	0
Approach	139,436	36	267
Measurement I	139,436	36	271
Retraction I	139,436	36	267
Approach II	153	36	271
Measurement II	150,543	36	275,9

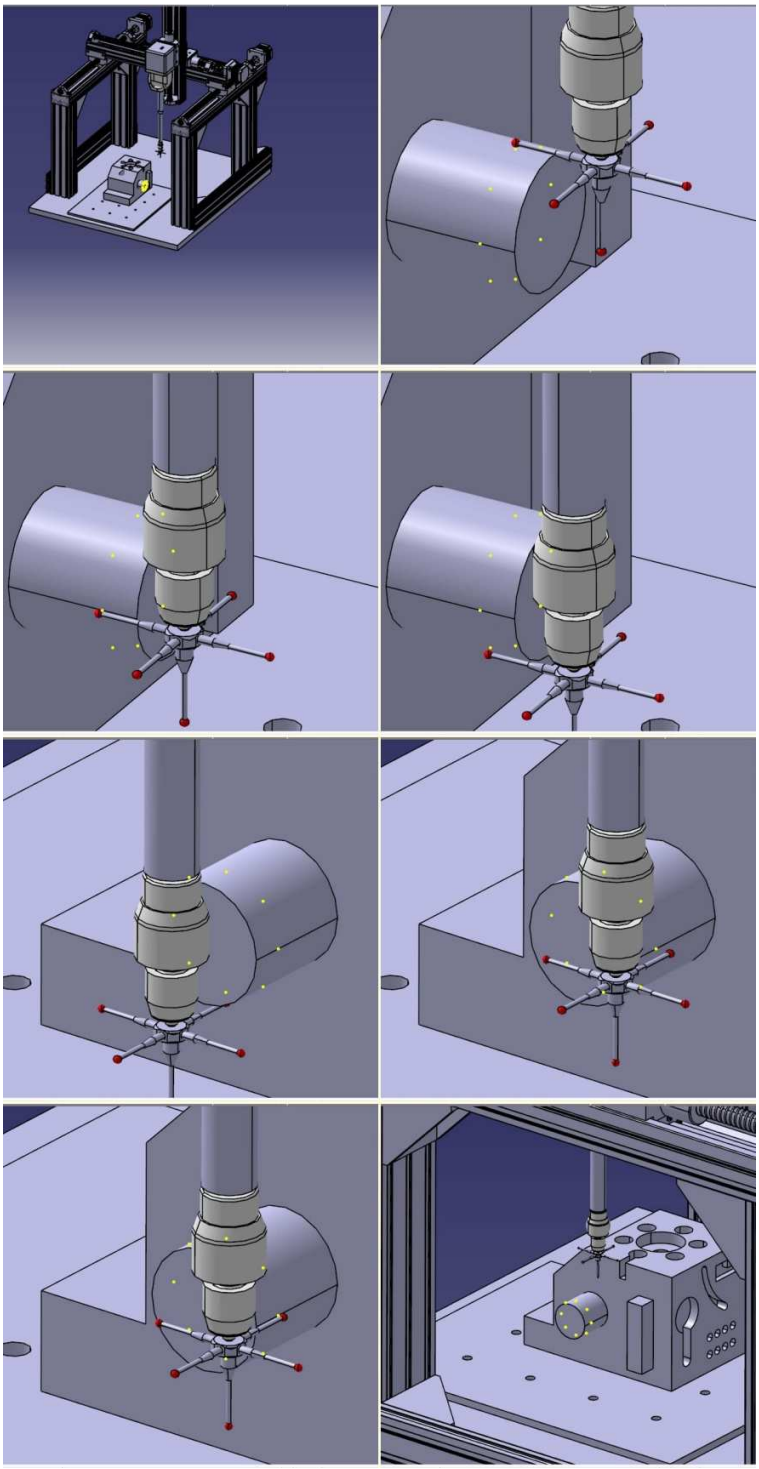

Fig. 7. Sample illustrations of the animation for the simulation process of the measuring procedure included in this text.

After the design had been made and the model uploaded into the CATIA V5 program a few simulation were performed, which showed the measuring process in a very transparent way. Using CATIA V5 program is educationally very useful as it is possible to examine every element at its measuring stage. Besides depending on the educational objectives it is possible to modify the model by adding some elements and thanks to the DMU Kinematics module we can prepare another simulations.

Even it is only virtual model and virtual presentation it occurs very useful in better understanding how CMM works. It's possible to prepare any 3D CAD model and then import it to virtual CMM model end prepare another simulation of measuring process.

Conclusion

The paper continues previous author works related with using 3D and virtual environment in engineering practice (Jakubowski, 2010, Jakubowski 2014).
At this stage the model is used for the educational purpose and because of this some issues which proves to be essential for the proper measurement model were omitted. For example, some construction elements, without which the actual model would not serve its function (e.g. divers – PC connection), were not included in the discussion. However all these elements do not affect the operation of the virtual machine.

Abstract

Higher Education is viewed in Nigeria, as in many other developing nations, as a critical contributor to national development. This is because of the belief that economic and social developments are driven more by the advancement and the application of knowledge. This belief has therefore made the Federal Government in Nigeria to keep playing a prominent role in the development of education in terms of funding and even governance. A National policy on education was therefore designed to chart the course of educational development in the country and has been a major reference point to both the public and private education providers. Higher Education funding has been described as the process of procuring and disbursing financial resources to tertiary institutions, for the provision of education of a given standard.

Keyword: higher education, funding, funding formula

1. Introduction

Historically, due to its importance to national economic performance, Higher Education funding has been the exclusive preserve of national Governments nationwide (Albrecht & Ziderman, 1992). This is also the case in Nigeria as funding of the Federal Universities is the sole responsibility of the federal government. All public universities are financed by grants/ subventions provided by either the federal or the state governments with very little or insignificant contribution by the students in terms of fees. Although there are quite a number of models for funding higher education globally, Nigeria Like many other countries where tertiary education is being sponsored by the government, uses the incremental budgeting system to allocate funds to the Federal Universities (Akinsolu, 1990; Olayiwola, 2012; Wangenge-Ouma, 2011).

2. The Budgeting for Higher Education

Initially, budgeting for higher education revolves around the NUC due to its advisory role to the government (Omoregie & Hartnett, 1995). The commission is expected to collect all budget requests

from the Federal Universities and scrutinize them to ensure complete compliance with the provisions of the funding parameters as approved by the government. The reviewed proposals are then recommended and forwarded to the Federal Government for funding. A budget defense session, coordinated by the National Assembly, will require all the universities to defend their budgets and allocations will be done on that basis. Notification of allocations will be forwarded to the NUC by the Federal Ministry of Education and each university is expected to prepare its operating budget based on the actual allocations, using the parameters set by the NUC.

The Commission, as the supervisory agency responsible for the management of all the universities in Nigeria, is also saddled with the responsibility of distributing the Federal Government's block grant allocations to the federal universities. The approved grant is further divided into recurrent and capital allocations, and is expected to be distributed in the ratio provided by the NUC funding parameters. Based on the provisions of the funding parameters (as presented below), the universities will prepare their operational budgets for the approval of NUC, and subsequent fund allocation. Thus the entire budgeting process is guided by the NUC funding parameters.

Besides this, the commission stands between the universities and the federal government, thereby insulating them from direct political control. They also ensure that these universities are fully accountable to the government, especially with respect to national policy implementation. As such it acts as a control agent for the federal government and ensures that the ethics and the standards of higher education, as defined by the government, are fully maintained.

3. Funding Parameters

To carry out its statutory role of receiving block grants from the Federal Government of Nigeria, with a view to distributing same to the Federal Universities, the National Universities Commission devised a formula called "National Universities Commission Resource Allocation Parameters" which it uses to allocate funds across all the federal universities in Nigeria (Akinsolu, 1990). These parameters are as given below:

1.	Enrolment specifications		
	Science based disciplines (including engineering)	60%	
	Social Science disciplines	25%	
	Humanities		15%
2.	Student/ Academic staff ratios		
	Art based disciplines		15:1
	Science based disciplines	10:1	
	Medicine		7:1
	Education		24:1
3.	Academic staff structure		
	Professorial grades		15%
	Senior lecturers	25%	
	Other lecturers		60%
4.	Non-teaching support staff ratios to academic staff		
	Senior administrative support staff	1:12	
	Senior technical support staff		1:2 (in science) 1:4 (in other units)
	Junior Staff		
	Junior technical staff		1:3 (in science) 1:4 (in other units)

5. Allowances for direct teaching and services. This is based on the level of intensity of student teacher contact, facilities and other teaching equipment required.

Art and education based disciplines 15 - 20% of staff salaries in the discipline
Science based disciplines 25 – 35% of staff salaries in the discipline

6. Line items funding

Library to total operating costs	5%
Teaching and research equipment to total operating costs	5%
Research and development to total teaching costs	20%
Public service to teaching costs	10%

7. Administrative support cost for each university
   - Central administration. Calculated on the salaries and goods & services required by all non-academic staff located in academic departments and units. The number of such personnel shall be determined from the approved number of non-academic staff whose salaries have been established under academic departments.
   - Student services. This shall include the costs of students feeding; maintenance of student's hostels and cost of student's sporting facilities. Note: feeding has however been suspended since 1988.
8. Other services.
   This includes the provision of university health services and the maintenance of university grounds and properties and facilities. While the cost of university health services is calculated per annum per staff member and his family, the cost of physical facilities is estimated on the needs of the particular university, as well as the size of its physical plant and land area.
9. Non-academic expenditures (personal emoluments).
   This includes leave passages, housing allowances and transport allowances, the allowances are calculated based on nationally approved rates and the total number of staff approved for each university.
10. Retirement policy: 1% of the university's total operating expenditure, as approved by NUC.
11. Local Income (Internally Generated Revenue)
    This includes receipts from various student fees charged by each university (e.g. accommodation, ID Cards etc.), rents on university properties, interests on bank deposits, and external grants received by the universities. The recurrent grant for each university is the NUC recommended expenditure, less the amount of local income. The Commission has directed all universities to raise at least 10% of their approved recurrent expenditure as internally generated revenue.
12. Total Salaries:
    This is estimated by calculating the average salaries of the recommended mixes of staff, by rank, in particular university functions, i.e. teaching, research, technical, administration, maintenance etc. and the number of staff allowed in the particular functions. Non-salary emoluments are similarly obtained from the product of the current rates approved by regulation and the recommended number of staff in each category.

Expenditures at the Federal Universities are divided into

1. Direct teaching expenses (salaries and wages of academic staff and their supporting staff),
2. Non-academic expenses (laboratories, libraries, research etc.) and,
3. Administrative support.

Direct teaching expenses are expected to be the largest of these three, as the essence of the University system is the provision of teaching and learning. To this effect therefore, the NUC funding parameters, as explained above, has recommended that all the universities must at least allocate nothing less than 60 percent of their total expenditures for direct teaching and academic activities, as shown in the table below

Table 1: Parameters for line items in recurrent grants calculations

Heading	Description	As % of recurrent expenditure
Teaching and Learning	Direct Teaching	32.6%
	Teaching support	1.6%
	Teaching research and equipment	5%
	Staff development and training	2.3%
	General academic expenditure	1.2%
Research and Development	Research	10%

Source: Adapted from; Olayiwola (2012)

But despite the existence of the above elaborate parameters the commission has been incapacitated and has been forced into haphazard allocations due to insufficient funding by the federal government (Albrecht & Ziderman, 1992). Thus Okoroma (2007), believes that the NUC has lost its capacity and capability to adequately supervise all the universities in Nigeria.

4. Funding Trends

Grants for recurrent and capital expenses of the Federal Universities are obtained from the Federal Government, as university education is supposed to be free in Nigeria. Historically, funding for the Federal Universities have been fairly steady, with universities receiving almost the full value of what they requested from the government. The discovery of oil and the subsequent economic boom witnessed by the Nigerian economy in the early 1970s made the Federal Government to abolish school fees and took it upon itself to provide full funding for the Federal Universities (Okebukola, 2010). Prior to 1975, all the 6 federal universities in the country are fully and sufficiently funded. This led to an increase in the demand for higher education, which made the government to establish additional tertiary institutions, especially federal universities.

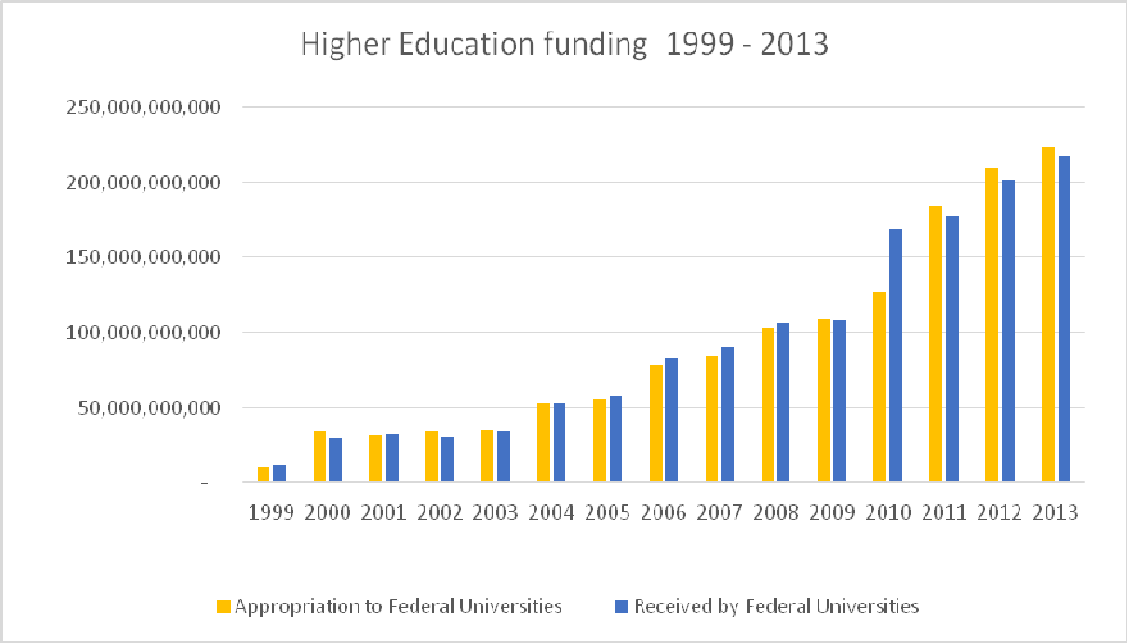
Table 2: Total Fund allocations to Federal Universities for the period 1999 – 2013

	Appropriation to Federal Universities	Received by Federal Universities	Number of Universities	Average per University	Exchange Rate N to $	$ Equivalent
1999	10,507,388,580	11,831,930,272	24	492,997,095	93	5,318,200
2000	33,788,940,312	30,143,004,498	24	1,255,958,521	102	12,301,259
2001	31,844,324,846	32,646,410,862	24	1,360,267,119	112	12,151,752
2002	33,778,450,500	30,351,483,193	26	1,167,364,738	121	9,650,035
2003	34,411,319,280	34,203,050,936	26	1,315,501,959	129	10,169,310
2004	53,024,557,483	53,466,287,486	26	2,056,395,673	134	15,403,713
2005	55,921,243,975	58,275,967,609	26	2,241,383,370	132	16,960,903
2006	78,066,798,858	82,376,684,290	26	3,168,334,011	129	24,627,548
2007	84,464,710,606	90,565,259,337	27	3,354,268,864	126	26,657,147
2008	103,858,443,524	106,633,620,745	27	3,949,393,361	119	33,308,538
2009	109,209,812,356	108,600,310,930	27	4,022,233,738	149	27,016,616
2010	127,465,208,169	168,955,649,920	27	6,257,616,664	150	41,634,176
2011	184,695,666,017	177,525,439,322	35	5,072,155,409	154	32,966,043
2012	209,498,125,598	200,768,495,246	36	5,576,902,646	158	35,408,906
2013	223,482,973,079	217,549,942,696	40	5,438,748,567	161	33,865,184
2014						

Source: National Universities Commission

However all this came to a sudden halt when the oil boom era was over. Government grants to not only the Federal Universities, but to the entire education sector came crashing. The government, after reducing the size of its grants to the Federal Universities, also attempted to increase the amount of fees payable by students, which was violently rejected by the students union (Okebukola, 2010). Although the funding pattern has seen some improvements from 1999, when a civilian government was sworn in, the increase was only nominal, as the purchasing powers of these grants has significantly dropped due to inflation, currency devaluation, economic and political turmoil and the impact of structural adjustment program (SAP). The number of universities was also increased from 24 in 1992 to 40 in 2013, which further stressed the financial stability of the Federal Universities. The annual grants to the education sector by the Federal Government from 1999 to 2013 is shown in Table 2. A comprehensive analysis of the table will be presented in the appropriate sections in this research.

Figure 1: Graphical representation of total fund allocation to Federal Universities in Nigeria 1999 – 2013

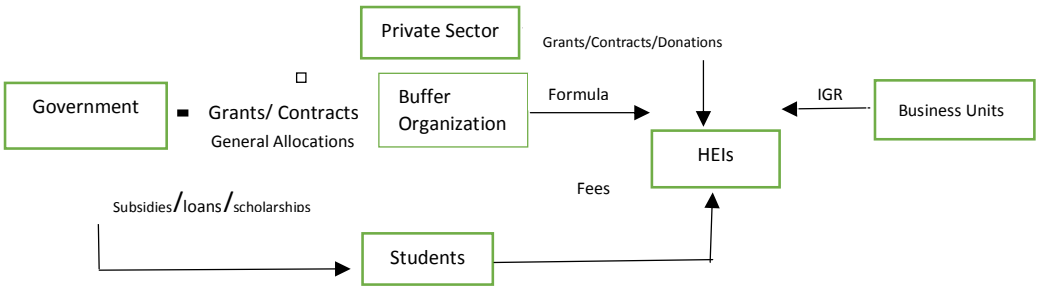


Source: National Universities Commission (NUC)

5. Sources of funds for Higher Education in Nigeria

HEI funding is a very serious issue for most national governments, as they form part of their major steering mechanisms through which they control the HEIs, and are as well linked to national policy issues (Barr, 2004; Jongbloed, 2004). Besides the level of resources allocated to the HEIs, what matter most is the funding mechanism as well as the criteria used for its allocation. The composition of funds, to a great extent, determines an Institution's level of freedom, and is likely to determine its internal governance (Lepori et al., 2007). The figure below depicts a simple representation of the main channels of funding higher education in the developed and as well as in the developing nations like Nigeria.

Figure 2: Sources of funds for HEIs



Source: Adapted from Lepori et al. (2007); Saint et al. (2003); and Jongbloed (2004).

Figure 2 above is a graphic representation of higher education funding channels in the developing and in most developed countries (Jongbloed, 2004), and is further explained thus;
Government allocations:

This is the major source of funds for the Federal Universities in Nigeria. Government grants and allocations constitute about 85 percent of the total income received by the universities (Akinyemi, 2013). The grants are contributed for the running of the HEIs by the Federal Government and are being channeled through the National Universities Commission.
Grants/ contracts from Government;

These are funds specifically allocated to the universities for particular projects or activities, for defined periods. They include research grants received from research funding agencies, grants from international bodies like the World Bank and UNICEF etc. In Nigeria for example, such funds are coming from the Tertiary Education Trust Fund (TETFund). The trust fund was established by the Federal Government to raise funds for tertiary education, thereby reducing their reliance on the Government. A 2% education tax on the profits of all corporate organizations registered in the country, was therefore charged by the Federal Government and is being collected by the agency for the development of tertiary education. The Fund is a major source of financing for capital projects for the tertiary education sector in Nigeria. Between 2008 to date, the fund has allocated over Six Billion Naira for the development of tertiary education (as is shown in Table 2.2). It should however be noted that the intervention provided by the Fund does not fund teaching and learning.

Table 3: Volume of funds allocated by TETFund for Tertiary Education in Nigeria for the period 2008 – 2014.

TOTAL INTERVENTIONS BY TERTIARY EDUCATION TRUST FUND (MILLIONS)								
	2008	2009	2010	2011	2012	2013	2014	TOTAL
Capital Projects	107.00	132.50	431.87	469.90	763.00	814.00	1,248.00	**3,966.27**

Source: Tertiary Education Trust Fund (TETFund).

Grants/ contracts /donations from private organizations

These represents grants or donations received by the HEIs from private business organizations, like corporate bodies. The funds could come in the form of charities or endowments to fund specific activities or projects within tertiary institutions. Some of the organizations that are currently supporting the HEIs in

Nigeria, according to Ogbogu (2011), includes John D. and Catherine T. MacArthur Foundation, The Ford Foundation, The World Health Organization (WHO) etc. Others, like Julius Berger PLC, CHEVRON and the Petroleum Trust Development Fund (PTDF) also contribute physical infrastructures for the development of tertiary education in Nigeria.

Student fees

These are fees collected from students either for tuition or for other educational charges by an institution. Tuition fees, by far, contribute the largest share of student fees received by the HEIs. These fees are classified into undergraduate and postgraduate fees. In most nations, especially in developing nations like Nigeria, undergraduate tuition fees are free and funding is provided by the government, and where charged, such fees are set by the government. Postgraduate tuition fees are however left at the discretion of the institutions to charge at their convenience, as majority of governments do not subsidize postgraduate education.

Internally Generated Revenues

These are funds mostly generated by the HEIs from their internal business and commercial activities to boost their income base and reduce their over reliance on government funds. They include incomes like; interest earned on bank deposits; charges for hostel accommodation and fees from consultancies and other related incomes. According to the NUC funding parameters, each university is expected to raise at least 10% of its operating expenditure internally (Omoregie & Hartnett, 1995).
It should be noted however that the choice of the funding mix for the institutions depends on the governments perception of the visions and missions of higher education in any given nation and the perceived role of education in national development (Omoregie & Hartnett, 1995)

Abstract

The paper is focusing on selected aspects of country-of-origin brands based on the results of primary representative researches conducted in Slovakia and the Czech Republic combined with additional information concerning the current practice. It highlights the brand importance within the frame of consumer preferences, opens the discussion concerning Slovak and Czech brands background and compares selected attitudes of the Slovak and Czech consumers toward brands.

Keywords: brand, consumer behavior, country of origin, Slovak brand, Czech brand.

Introduction

The issue of country of origin of the brand is a problem that has never been subject to systematic scientific research. It rarely appeared in marketing research focusing on customer preferences or in the monitoring of consumer behavior. Such studies are currently conducted in many countries according to Donvito and Tiziano (2015), including Slovakia and the Czech Republic (note: current examples in this field are represented by surveys conducted by TNS Slovakia – Lifestyle (2015), the CPS consumer panel by GfK Slovakia (2013a), or typology of Slovak and Czech consumers based on the MML – TGI by research agency MEDIAN (2015), concerning the Czech Republic it is also possible to mention surveys conducted by Stem/Mark (2015)). This paper aims to focus on consumer brand perception according to the results of two representative research studies taking place over the years of 2013 and 2014. Both research studies were conducted by institutions of higher education. The questions were formulated in order to compare the answers of both the Czech and Slovak consumers.

The first survey was conducted within the research project VEGA 1/1051/1 Analysis of strategic processes of brand building and brand management in the context of homogenization and individualization of consumer needs by the Department of Marketing at the Faculty of Management, Comenius University in Bratislava. Data were collected in the period of January to April 2013 and its primary objective was to analyze the attitudes and preferences of Slovak consumers towards brands and branded products with special attention to identify the impact of brands on purchasing behavior of the Slovaks. Primary research was conducted on a sample of 1067 respondents – consumers.

A similar research study was conducted by the Department of Marketing Communications, Faculty of Multimedia Communications, Tomas Bata University in Zlin. Data were collected from a sample of 1022 respondents in the period of October to November 2014. As we have already indicated above, the questions were semantically similar and formulated in a way that would enable us to compare the research results in the Czech Republic and Slovakia. In both cases the sample group reflected the composition of the population older than 16 years and the form of proportional stratified selection was applied. The youngest respondent in the Slovak research study was 16 and the oldest 81 years old. In the Czech Republic the youngest respondent was 16 years old too, however, the age range was set at

60 and more. Selected statistical methods were used for data processing. The purpose was processing of the obtained data into a form suitable for scientific work and economic practice.

The research method used in both surveys was questioning – respondents were supposed to answer three open questions and thirty-two closed questions in a form of Likert scale, one of the most used and most reliable techniques measuring attitudes. Respondents in both surveys could answer in a five-point Likert scale starting at "I totally agree" and ending at "I fully disagree", the median was the answer "I do not know".

In the case of open questions, we were looking for the answers to the question which brands respondents consider Slovak or Czech and why. Respondents' answers were compared but taking into consideration their diversity and the difficulty of their comparison, they, however, raised more questions than answers. Although respondents' replies raised new problems, at the same time they brought new ideas in the field of marketing research focusing on exploring brands. The process of assessing results of these studies brought many surprising answers – these make us think about what is and what is not a "domestic" brand.

Brands and consumer preferences

The issue of consumer preferences is a complex topic. What consumers prefer and why depends on a number of rational and emotional factors entering into the decision making process. The fact that the decision on the purchase of goods and services depends on preferences and experience of consumers has long been known. However, consumers do not always make decisions based on their own preferences. Their decision making is often determined by other attributes – these enter into the process and influence it. These include: the availability of goods and services, pricing, media communication (poor hypermarkets), own and other's experience – both positive and negative, lifestyle, preferred behavioral patterns, and a number of economic factors. Decision criteria vary, they depend on the fact whether durable products or fast moving consumer goods will be purchased (note: the GfK Slovakia Agency has been monitoring consumer behavior in Slovakia for several years. Its first results showed that for durable products, such as washing machines, refrigerators, or televisions, Slovak consumers prefer branded products to non-branded ones (2013b)). Nowadays, many Slovak companies want to build a brand. Customer preferences are in favor of branded goods and services; selection of non-branded goods and services is rather random. Brand-building is recommended to all entrepreneurs who are able to provide quality products and guarantee their quality by literary and other sources (according to: Aaker (2003), Cernatony (2009), Taylor (2007), Keller (2007), Hesková (2006), Smolková et al. (2013), Smolková and Štarchoň (2013) etc.). All authors point to the fact that this is a long term and resource intensive process, which, however, creates the desired effect.

Brand Slovakia and Slovak brands – Brand Czech Republic and Czech brands

Before we begin to think about what brands are considered Czech or Slovak and why we need to understand the brands of these two countries and to take into consideration their common history. Some brands named in the survey by consumers were established and used in the common state of the Czechs and Slovaks. Brand building applies to the country of origin and to the country where the brand comes from, and it may also apply to the country in which products, under certain brand, are produced. If we talk about customer preferences, we must take into account the real characteristics of the countries we are talking about. Without these, no realistic picture can be made concerning the sale of branded products on a specific market, what brands are offered on it and therefore it is not possible to talk about the specifics of the business environment or customer preferences. The European Union has paid a lot of attention to the fact that individual Member States have enough space to build their own

brand – e. g. changing EU Presidency and the possibility of supporting marketing activities. It named products that have a national characteristics and the trademark of the country. The types of trademarks in the EU include: protected designation of origin (PDO) – Paprika from Zitava or Saaz Hops (Žatecký chmel); protected geographical indication (PGI) – Slovenská bryndza cheese or Czech beer; traditional speciality guaranteed (TSG) guaranteeing the accuracy of the recipe not the brand of producers (Bratislavský rožok/Pressburger Kipfel/Pozsonyi kifli or Třeboň Carp) as mentioned in The industrial property office of the Slovak Republic (2015) and Eurostat (2015).

Through the support of regional development, the European Union prefers sales of traditional products – this goes hand in hand with the development of tourism and so it supports activities to promote a particular country. The Czech Republic and Slovakia were established in 1993 and it has to be said that recently the Czech Republic has been more successful in brand building of their country, particularly as a country of original products (Czech beer), a tourist destination (according to The state agricultural intervention fund (2015) in the polls Prague has performed as an attractive tourist destination in the long run). Unfortunately, despite numerous opportunities it can be stated that the brand Slovakia as a country of origin or as a tourist destination has so far been undistinguished and succeeded only in few branches, for example in the automotive industry. The Czech Republic and Slovakia are countries situated in Central Europe, both of them are EU Member States, and Slovakia is a member of the monetary union too. The population of the Czech Republic amounts to 10.5 million and the Slovak Republic to 5.5 million inhabitants. Both brands, due to their common history, can be considered specific in terms of consumer preferences, in relation to brands and to the behavior of business entities on both markets.

A number of companies, which had been met by consumers for decades, closed down and a large part of production considered traditional and hence domestic disappeared with them. This is particularly true of agricultural production, both plant as well as animal, footwear and textile industries. We can only assume whether these businesses had closed down if they had had invested in the systematic building and proper positioning of their brands in the past. Those businesses which owned a brand and were building it up had two basic options – to develop it or to deal with it as if it were business goods. A number of brands, originally created in Czechoslovakia, have become part of the portfolio of big foreign companies, however, even when the brand and production associated with this brand became part of the portfolio of multinational companies, most producers have kept production, or at least part of it, in their countries of origin. It is possible to identify those companies that transferred production abroad (examples include: Slovak Palma Tumys brand – its production moved abroad in 2012; the traditional Czech brand Zetor became part of the Slovak HTC holding company in 2010; the traditional Slovak producer of poultry Hyza has been in the hands of the Czech Agrofert holding company since 2006). Part of brands traditionally seen as Czech or Slovak became part of the portfolio of global holding companies, others are owned by Czech and Slovak owners. In both cases, however, the brand is built in relation to the place of production because the volume of domestic sales is a factor on which companies owning the brand count.

The growth of domestic sales is affected by the support of country of origin labels (even though it cannot be said that it is the support of domestic production as all the governments have preferred FDI inflows to the support of domestic producers). According to The state agricultural intervention fund (2015) in the Czech Republic, products fulfilling high-standard requirements are awarded by Klasa Awards “Top Quality Czech Product”, and as identified in Superbrands Czech Republic (2015) successful products are awarded within Czech Superbrands Awards. In Slovakia there has been a tendency to support domestic production for twenty years, since SK Quality Brand as it is published by Ministry of agriculture and rural development of the Slovak Republic (2015) is granted and the project by the Foundation Slovak Gold (2015) takes place. In addition, intensive media campaign to promote domestic sales has been run in Slovakia since 2013, in which Slovak products are labeled by Quality of

Our Regions published by INCOMA Slovakia (2015). Civic association of the same name, responsible for the initiative, does not grant quality certificates but it registers companies producing items in Slovakia and it aims to educate Slovak consumers. In the Czech Republic a similar campaign has taken place since 2014 and as published by Nadační fond Český výrobek (2015) it is recognizable by the logos "Genuine Czech" and as published by Ministry of agriculture of the Czech Republic (2015) „Regional food". The logo "Genuine Czech" aims to promote Czech producers not only on its own domestic market. One of their requirements is that the company must be Czech using only Czech capital. The logo "Genuine Czech" is granted by the Federation of the Food and Drink Industries of the Czech Republic (FFDI) and guarantees the maximum possible rate of Czech ingredients in food products. The logo "Genuine Czech" indicates that the product is made in the Czech Republic and the producer employs Czech employees. The logo "Local product" is granted to Czech products with regional tradition. These include local food and traditionally made products (jewelery, ceramics, product made of wood, glass or textile), and environmental factors are emphasized too.

Quality award in an international context is another important factor because it has an international impact and aims to promote Slovak and Czech brands worldwide. Philosophy to promote domestic production of both goods and services has been adopted by many foreign corporations and taking the advantage of domestic sales they have realized that many Slovak and Czech brands have a greater potential for growth in foreign markets but the existing owners and their managements have so far failed to take advantage of this potential.

The support of domestic producers has experienced unprecedented sales growth in domestic production and is still persisting. Czwitkovics (2013) mentioned that it is connected to the heavily promoted need to promote the domestic economy by own domestic consumers. Ethnocentrism of domestic consumers and country of origin brands are encouraged. Activities promoting the sales of domestic production are in relation to influencing customers so as to take note of the identification codes on the product packaging and "not to take a look at the price" because domestic production in smaller countries is not always the cheapest in the given segment. Should the price be not the critical factor in the process of decision making of the Slovak and Czech consumers, it is necessary to build brands but above all to increase the quality of domestic production.

What brands are Czech/Slovak?

The answer to this question should be simple, but in fact it is not. As we have indicated, we are unable to clearly say what a Czech or Slovak brand is. Criterion, as is clear from the title of this paper, is determined by the country of origin of the brand. A lot of specialists, however, think that this criterion is insufficient, others are not interested in the country of origin but tradition, and others would rather investigate ownership relationships. So what are the criteria? Three basic criteria will be outlined below.

The first criterion is tradition and it applies to a) typical products such as Czech beer or jewelry, Slovak sheep cheese, Moravian or Tokaj wine; b) brands, if established in the territory of the Czech Republic, respectively Slovakia or the former Czechoslovak Republic, no matter on which markets they now operate. One example of such a traditional brand is Bata, which appeared as Czech and Slovak in both surveys. Its founder, Tomas Bata, created it in the period between the two world wars in the former first Czechoslovak Republic and produced products in parallel in the territory of the Czech Republic (Zlin) and Slovakia (Svit). In the Slovak survey, 2% of respondents marked it as a Slovak brand; in the Czech survey, the number is even higher – 4% of respondents marked it as a Czech brand. After World War II, Bata transferred his business activities to Canada, where the Bata brand is currently perceived as their own brand.

The second criterion is the country of production or service provision. In the Czech survey, the question: What do you think of when you hear the expression "a Czech brand"? was answered by mentioning brands such as Skoda, Pilsner Urquell, and Kofola. In the Slovak survey, brands like Rajo, Jednota Coop, and Figaro were mentioned. Furthermore, part of Slovak respondents considered the Kia brand for Slovak. KIA Slovakia has positioned itself this way. A similar example can be seen in the Czech Republic where Hyundai does the same.

The third criterion presents ownership relationships. Brand is judged according to the country of origin or nationality of those who created it. Examples of Slovak brands were given by respondents, such as ESET, Hyza (which has meanwhile become part of the Czech Agrofert company), or Sedita; Czech respondents named Skoda, Kofola, and Opavia. This criterion, however, is the most difficult to grasp for both, respondents and researchers. Information on which brand belongs to the portfolio of which multinational corporations is not always communicated or publicly known. As shown by both studies, it may not be so important for consumers to look up data relating to the brand ownership and their decisions are not based on these data.

The problem is that none of the criteria mentioned above is comprehensive, and, in some cases, these criteria cannot be verified. The place where the brand was created does not need to be identical to the market on which it operates. On the European market, and this is also true of the Czech and Slovak market, we can see the presence of many different brands. Brands, local but also global, operate here – some have outsourced manufacturing activities wholly or partly to the territory of our countries, some focus their production and brand building on a single market. Therefore what is important – is the viewing angle and not a strict determination of the distinguishing criteria. If it is a macroeconomic view the information on where the products offered under a given brand are manufactured (or service is provided) is the most important factor. If marketing view dominates, the country of origin of the brand is important in terms of image perception of the country and the country as a brand as well as brand loyalty on a particular market.

Nowadays, some traditional Czech and Slovak brands, and it has to be said that this also applies to the most successful ones, are in the portfolio of foreign holding companies. Brand managers of big global companies either kept or rebranded the names of originally Czech or Slovak brands. They are aware of the importance of the country of origin of the brand because this plays a significant role in consumer preferences. The survey shows that consumers perceive brands historically created in the particular territory as domestic ones. This fact cannot be ignored, it is necessary to take it into consideration and to make the most of it. Therefore, in the Czech Republic and Slovakia, and many other countries, annual research is done on the following: what brands are most successful and why, moreover, rankings of successful brands on global, European, and national markets are made. The Superbrands Czech Republic (2015) project awarding the most successful brands in the Czech Republic and Slovakia as published by Superbrands Slovakia/CEE (2015) can be mentioned as an example.

The sales volume of branded products is increasing and there is a high level of probability that this trend will continue. As we have already mentioned above, the existing criteria for determining the country of origin of the brand vary a lot and a range of factors are taken into account. Surveys of customer preferences are always localized to a particular country or region. Legislative standards, cultural traditions, educational level and other economic and social factors can have a quite significant influence on how respondents will answer. Surveys summarize factors valid in other parts of the world if it is assumed that deviations are not statistically significant. Customer preferences depend also on other factors that have not been mentioned yet: purchasing power, regional distribution of wealth in the country, the possibility to make a choice among several branded and non-branded products, existing offer on particular markets, consumer ethnocentrism and many other factors influencing purchasing behavior. A question can be asked: How many people would prefer branded products if they could

afford it? In many regions in the Czech Republic and Slovakia, price is the determining factor in buying decisions – this fact has been proven not only by our surveys but also by surveys conducted by reputable agencies. Concepts supporting domestic production in both countries, the Czech Republic and Slovakia, affect customers and encourage them to buy domestic products. But the fact is that among EU Member Countries, the Slovak Republic has the second smallest offer of country of origin products. Although the Czech Republic is statistically doing better, the import volume is increasing at the expense of Czech production from year to year (note: published statistical data are mainly related to food products and assessed in terms of food self-sufficiency. Comprehensive data on total production are not available.). This is one of the main reasons why both the Czech and Slovak governments decided to influence customer preferences according to the country of origin. The objective of this policy is easy to read – it is economic development, employment growth and support of domestic entrepreneurs. A secondary consequence of such activities is to support processes linked to creating and positioning of brands. Without a brand – a fundamental distinguishing element – it is very difficult to identify goods or services. Therefore, in the Czech Republic and Slovakia, most companies work on brand building and those who have not done it yet think about it.

As it has already been indicated, the initiative to prefer domestic production is far away from being unique. Governments of many countries in the world support sales of domestic brands. They want to be sure that subsidies (if provided) are directed to companies having an impact on the growth of domestic economy. Governments initiate concepts to support domestic production for different reasons, but they also wish production to be "returned" to countries where brands were created and are operated. The reasons are mostly strategic and tactical; it can be lower transaction costs, failure of the strategic partner, increase of the bargaining power or an effort to attract companies that have transferred their headquarters back to the country of origin. One of initiatives of many governments, this particularly applies to the Slovak government, is intensive brand building, for example intensive brand building of the Slovakia brand in an international context in order to ensure sales of products offered under this brand on the global market. These activities of politicians will also take place in the future because multinational corporations regularly "threaten" to relocate their activities to other countries or to stop production of one of the brands created on that particular market and which in terms of sales volume do not fulfill the expectations of managers.

Selected attitudes of Slovak and Czech Consumers towards brands

Within the solved topic and the previous framework concerning Slovakia and the Czech Republic, brand background followed by the results of two representative researches it might be interesting to compare attitudes of the Slovak and Czech consumers towards brands. Due to limited space given by the paper size it is not possible to make a comparative study covering all the achieved results resulting from the particular questions and the descriptive approach concerning the comparisons prevails. Only few selected attitudes are discussed. The first comparison is concerning quality perception of the Slovak and Czech consumers that were involved into researches, followed by their willingness to do shopping with or without trusting and preferring domestic brands and finishing by their perception of availability of foreign brands. Finally particular results based on weighted arithmetic average of respondents' attitudes toward the importance and influence of country of origin on brand perception are outlined.

As can be seen in Fig 1, quality of Slovak and Czech brands exceeds the average value. Respondents' answers on a scale from I totally disagree to I fully agree relating to the statement "Czech/Slovak product are of high quality" indicate that from their point of view the quality of Czech and Slovak brands is not poor. It can also be stated that domestic producers are more trusted by the Slovaks than by the Czechs.

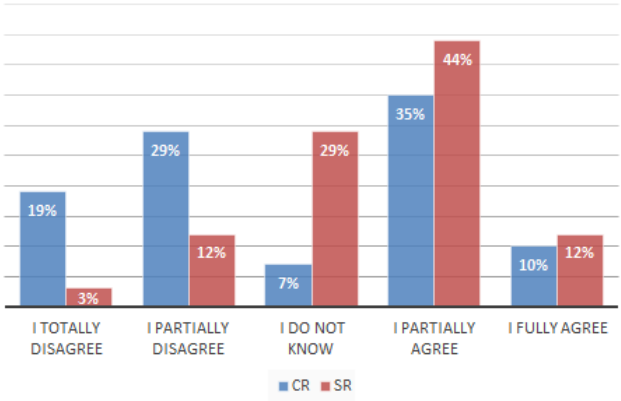

Fig 1. Quality perception of the Czech and Slovak brands – domestic products are of high quality (source: own)

According to the surveys containing the statement related to trust and willingness to do shopping, preferring Czech/Slovak brands it is necessary for domestic producers to build their brands because the willingness to buy branded products also depends on respondents' attitudes towards the Czech Republic, respectively Slovakia (Fig 2).

Most companies doing business in the Czech Republic or Slovakia and operating in these markets expect political and economic steps leading to creating a functioning system for supporting domestic entrepreneurial activities, and conditions for building country of origin brands should be created too. Such a system should favor domestic brands, make them more visible, and create space for their further development. However, it can be said that the system supporting domestic brands does not work sufficiently in either of the two countries. Although there are activities but as they have been introduced they do not motivate entrepreneurs to invest in intensive building of Czech or Slovak brands.

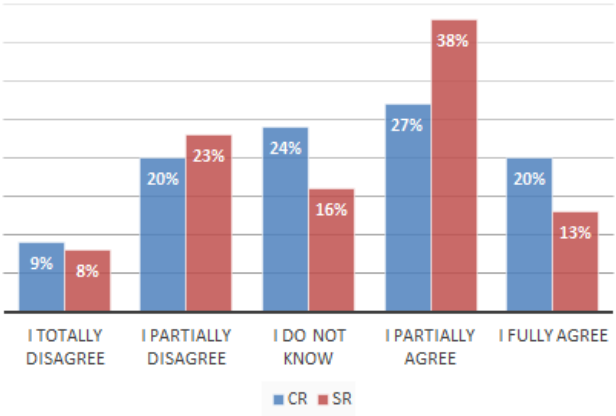

Fig 2. Are you more confident in Slovak/Czech brands than in foreign brands? (source: own)

This is different on the consumer side. They show confidence in domestic thus Czech/Slovak brands. Current Czech and Slovak consumers aged 16+ have experience with brands. They are targeted by campaigns promoting growth of the domestic economy and employment; they perceive the need for economic growth in the context of brand building of the country. But even when they try to prefer domestic brands when purchasing products, they do not always have such an opportunity because domestic production is either non-existent or limited, as can be seen particularly in the Czech survey, to certain regions. Moreover, the situation is worsened by problems related to the question of the accurate identification of the country of origin product.

As is shown by Fig 3 relating to the statement Foreign brands are more available than Czech/Slovak brands, consumers are frequently confused by the existing offer on these markets. Looking at Fig 3, it is obvious that in this case Czech consumers are more hesitant and undecided.

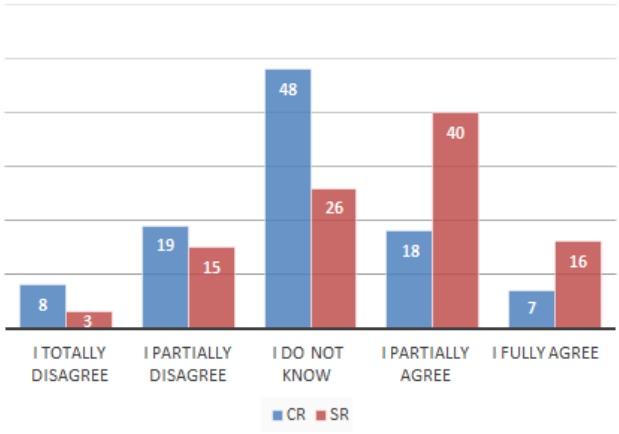

Fig 3. Foreign brands are more available (source: own)

Summary of results (weighted arithmetic average of respondents') importance and influence of country of origin on brand perception is illustrated in Fig 4.

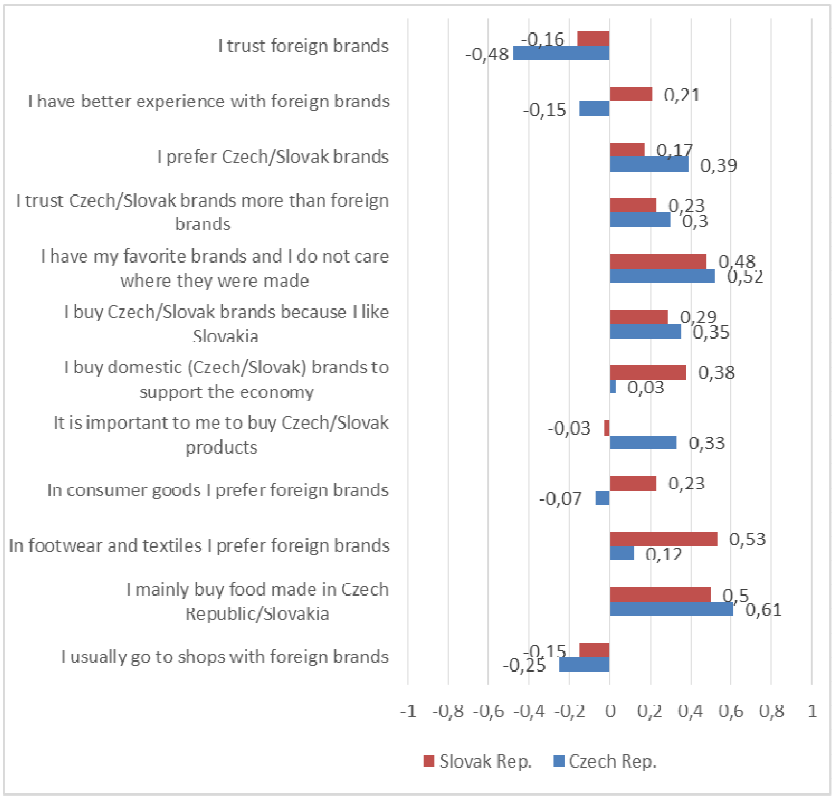

Fig 4. Attitudes of respondents' toward importance and influence of country of origin on brand perception (source: own)

From the results of two primary research it can be stated that the respondents are more focused primarily on domestic Czech and Slovak brands when buying food. This tendency is intensified among respondents from the Czech Republic, where it is in accordance with the result of higher orientation towards the domestic food and is generally less determined trust towards foreign brands than for respondents from Slovakia. The reason for the orientation to domestic brands among respondents in the Czech Republic and Slovakia is partly because they like their country. At the same time Slovak respondents prefer to buy Slovak brands to support the economy meanwhile respondents in the Czech Republic like to buy homemade products because it is very important for them. The orientation of Czech respondents to the Czech brands is in the footwear, textile and consumer goods, much lower among respondents in Slovakia.

Wider results concerning the Czech primary research are published by Štarchoň et al. (2015). Comprehensive results by Smolková et al. (2013) and partial results of the Slovak primary research were already presented and published by more scientific contributions, other papers and articles e. g. Olšavský (2013), Štarchoň and Weberová (2014) and Vilčeková (2014).

Conclusion

Representative surveys, whose results were analyzed in this paper, showed that customers in both markets prefer branded goods and services, and if they have the ability and opportunity, they will

prefer “domestic brands” to foreign ones. Of course, it depends on the fact whether they have such an opportunity. Perception of “domestic” brands may, however, be subject to a range of rational and emotional criteria. No unique criteria exist and research shows that it is impossible to consolidate them. The country of origin of the brand has always played and in the future it will play a role and it will be one of the important criteria in the selection of consumer products.

Recently, anyone presenting the results of research on customer preferences in relation to branded products has had to experience better orientation of consumers in the range of branded products and a fairly good knowledge of various brands of goods and services. Analysis dealing with when, at what consumers, in what segments and age groups a brand plays a role in the process of deciding on the purchase of goods and services vary a lot – in some analysis the country of origin plays a role, in others it can be the price or other factors entering into the decision making process. As it has been indicated above, customers do not necessarily select products of domestic manufacturers or service providers, in some cases offer of domestic production is insufficient or even completely non-existent. Therefore, the survey results have more or less only an indicative character and do not lead to clear conclusions, however, they are helpful in formulating recommendations.

Nevertheless, conclusions can be drawn from selected research results. As a result of the research studies, one of the conclusions claims that in the future, the Czech and Slovak markets will prefer brands representing value for customers and taking into account local customer requirements. Level of customers’ awareness is increasing from year to year and Slovak and Czech customers are more and more aware of the importance of the country of origin of the brand, especially in terms of product quality.

The Scientific Testing: Progress and Perspectives

Sevag Kertechian

PhD Applicant

Abstract

The scientific testing is a particular methodology within the field of management. In France, the term "scientific testing" is used to mark the distinction with the "legal testing". The scientific testing is a field experiment which allows an artificial reproduction of a potentially favorable situation in order to demonstrate unjustified preferences during a recruitment process. The objective of the testing is to reveal discriminatory hiring practices. However, and despite numerous testings, particularly in France, this method seems to suffer from an inaction in the managerial framework and weaknesses on the legal framework. In addition, this method tends to show its limits on the quantitative ground. Consequently, and to overcome these shortcomings, this paper pursues the dual objective of discussing managerial consequences of testing results and of a more complete approach of this method.

Keywords: testing, discrimination, recruitment, quantitative methodology.

Résumé

Le testing est une méthodologie particulière des sciences de gestion. En France, on distingue le testing scientifique du testing juridique. En effet, le testing scientifique est une méthode *field experiment* qui permet la reproduction factice d'une situation potentiellement opportune à générer des préférences injustifiées. L'objectif de sa mise en place, au moment du recrutement, est de révéler des pratiques d'embauche discriminatoires. En dépit des testings existants, et en particulier en France, la méthode semble pâtir d'une inaction sur le plan managérial et de faiblesses sur le plan juridique. De plus, cette méthode tend à montrer ses limites méthodologiques. Par conséquent et comme propositions à ces manquements, ce papier a pour double objectif de discuter des conséquences managériales des résultats issus des testings et de proposer une approche méthodologique plus complète.

Mots-clés : testing, discrimination, recrutement, méthodologie quantitative.

I. Le testing : généralités

Le testing ou test de correspondance est une méthodologie particulière des sciences de gestion. L'objectif initial est la mise en avant de pratiques discriminatoires au moment de la sélection des candidats sur CV. Aux États-Unis, la méthode est d'abord utilisée pour mesurer les discriminations raciales (Heckman et Siegelman, 1993). Il en va de même au Royaume-Unis où Hubbuck et Carter (1980) puis Brown et Gay (1985) s'intéressent à la discrimination à l'encontre des « indiens » et des « pakistanais »[1]. La discrimination à l'égard des personnes d'origine maghrébine est aussi l'une des variables la plus testée lors des testings (En Belgique : Smeeters et Nayers (1998) ; Aux Pays-Bas : Bovenkerk et al., (1995) ; En Espagne : Prada et al. (1996) ; En Allemagne : Goldberg et al., (1996). En

[1] Selon Moindrot (1965), l'immigration du subcontinent indien, et en particulier des indiens et des pakistanais, commence à la fin des années 1950.

France, il faut attendre les premiers travaux d'Amadieu (2005), en gestion des ressources humaines, et de Petit (2003), en économie, pour mesurer l'importance des testings. On entend par discrimination « *un traitement inégal fondé sur un critère illégitime. Il s'agit donc d'une action représentant un « désavantage » pour une personne ou un groupe de personnes en raison de critères non pertinents dans la poursuite de l'objectif sous-jacent à l'interaction, frappés du sceau de l'illégitimité, donc moralement et socialement non acceptables* » (Fibbi, 2005). En France et au sein des pays de l'organisation de coopération et de développement économiques (OCDE), les critères de la discrimination sont à quelques différences près identiques (discriminations fondées sur la « race », la couleur de peau, l'âge, le genre, etc.).

Ainsi, sur le plan théorique, nous discuterons des avancées en matière de testing (qu'est-ce qu'on mesure et quelles sont les objectifs) et des différences en matière de protection des victimes. Nous verrons notamment que les contentieux américains, en matière de discrimination, sont plus nombreux et les enjeux plus importants. Mais c'est sur le terrain empirique que les avancées sont les plus importantes où nous proposons une approche plus complète de la méthode du testing.

II. Discussions et voies futures de recherche

II.1. Apports managériaux du testing

Les cas constatés de discrimination en entreprise ne semblent pas s'estomper et l'environnement social et économique semblent favoriser les pratiques discriminatoires. Cette tendance se confirme avec le récent testing mené en France portant sur la discrimination religieuse (Valfort, 2015). Si l'objectif du testing est d'apporter des solutions managériales aux problèmes des discriminations, qu'en est-il en réalité ? Nous proposerons notamment une étude comparative des solutions managériales apportées par les testings.

II.2. Une méthodologie limitée ?

De plus, des limites peuvent être apportées à cette méthodologie de terrain (*field experiment*). En effet, selon Smeeters et Nayer (1998, p. 13), « *la méthode de recherche du test de situation met en œuvre une technique qui préserve la qualité de "**vie réelle**" de l'observation et évite la perspective anecdotique et subjective du récit privé d'acteur* ». Outre les limites inhérentes à la méthodologie (Heckman, 1998 ; Phelps, 1972 cité par Petit, 2003, p. 77 et 78), elle ne permet pas une approche compréhensive du problème et se contente d'analyser de manière quantitative la discrimination et ce à un stade initial (Piguet, 2001). Ces limites méthodologiques vont de paires avec les limites d'actions du testing et on peut se poser la question générale de savoir comment évaluer la perception des recruteurs avec la méthodologie du testing. Ainsi, nous proposerons une méthodologie complémentaire à la méthodologie quantitative du testing.

Conclusion

Ce papier a pour objectif de mettre en perspective les testings réalisés à un niveau international pour faire ressortir deux constats. Le premier concerne l'apport managérial issu du testing. En effet, nous proposons de nous interroger sur les actions qui sont menées à la suite de la constatation des discriminations. Le deuxième constat met en avant les limites liées à la méthode du testing. Nous avons rappelé que cette méthodologie reposait exclusivement sur une technique quantitative. Par conséquent, nous souhaitons proposer une méthodologie complémentaire qui puisse renforcer la compréhension des traitements différenciés.

Abstract

The aim of this paper is to analyse the migratory phenomenon, a case study for Romania, the causes underlying the population migration, the size of this phenomenon in Romania, as well as the economic, political, social and physiological effects generated both in the country of origin, and in the countries of destination and influencing with different degrees and on varied temporal intervals the local labour markets, resulting in adapting reactions.

Keywords: *migration, labour market, remittances, education market, business environment*

Introduction

In the last years, migration has become an important phenomenon influencing the decisions made in any country, due to the economic, demographic, social and psychological consequences it generates. In the last years, the migratory phenomenon has increased due to the social and economic problems generated by the economic crisis that had a higher impact on migrants and vulnerable categories both in the countries of origin and in the countries of destination. If, until now, in Europe, the migratory phenomenon was caused mainly by border liberalization for the Eastern countries, as new EU members, in 2015, it was also caused by the mass exodus of refugees, especially from Syria.

As regards Romania, the migratory phenomenon has started with the opening of borders in the 90's when a definitive migration, especially of the German population, but also of Romanian ethnics was seen. They were highly qualified people and they went to countries such as America, Canada, Great Britain, Austria, or medium qualified people who went to countries such as France or Germany (Suditu B.A et al, 2013).

Subsequently, the phenomenon has become more and more extensive starting with the Romania's accession to the European Union that allowed the free movement of labour. During this period, the migration to the Western European countries has intensified, especially to Mediterranean countries, such as Italy, Spain, Portugal or Greece (Dănăcică D. Et al,2010).

Material and methods

In order to meet the need of information to be used for presenting the subject to be discussed, a bibliographical research and a statistical research have been performed, through which data for the conclusions regarding the performed study were collected, processed and analysed. Statistical tables have been used by which data were presented in a tabular way. This is a method which allows the description of indicators on which the performed analysis is based, and the establishing of the existing connections between its component elements. Graphical representations have been used to emphasize the extent and/or variation of data subject to the statistical research in view of showing their evolution in time

Results and discussions

In a study performed in 2011 by Ambrosini et al., a profile of the Romanian emigrant is made. Thus, the Romanians that took the path to the Southern European countries have the profile of a low-qualified migrant (negative selection as regards the level of education), the migrant that went to USA or Australia has, mainly high qualification (positive selection), and the migrants to the Western European countries belong to all the categories (neutral selection).

The flows of low-qualified migrants have decreased as level and intensity, and their medium and long-term demand is also decreasing, being more restrictive as regards the types of professions and occupations of interest for the countries with stronger economies (Vasile Valentina et al, 2014).

By analysing the situation of migrants between 2008 and 2013, it is found that the number of Romanian citizens living in a foreign country for at least 12 months has increased from 1,922,805 persons in 2008 to 2,344,183 persons in 2013.

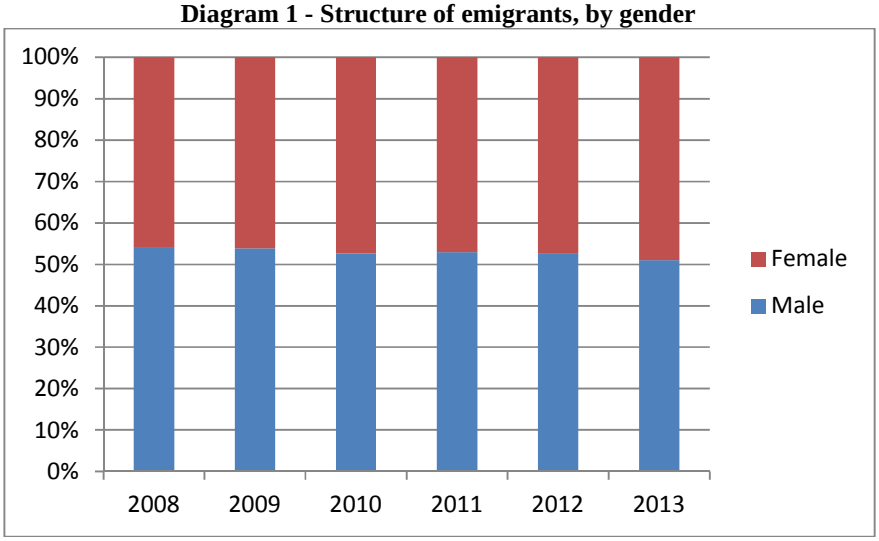
Table 1 - Situation of emigrants, 2008 – 2013

	2008	**2009**	**2010**	**2011**	**2012**	**2013**
Total	**1,922,805**	**2,135,691**	**2,234,155**	**2,288,531**	**2,341,263**	**2,344,183**
Male	1,041,256	1,149,822	1,192,763	1,213,082	1,232,536	1,196,324
Female	881,549	985,869	1,075,449	1,075,449	1,108,727	1,147,859

Source: AMIGO, 2012

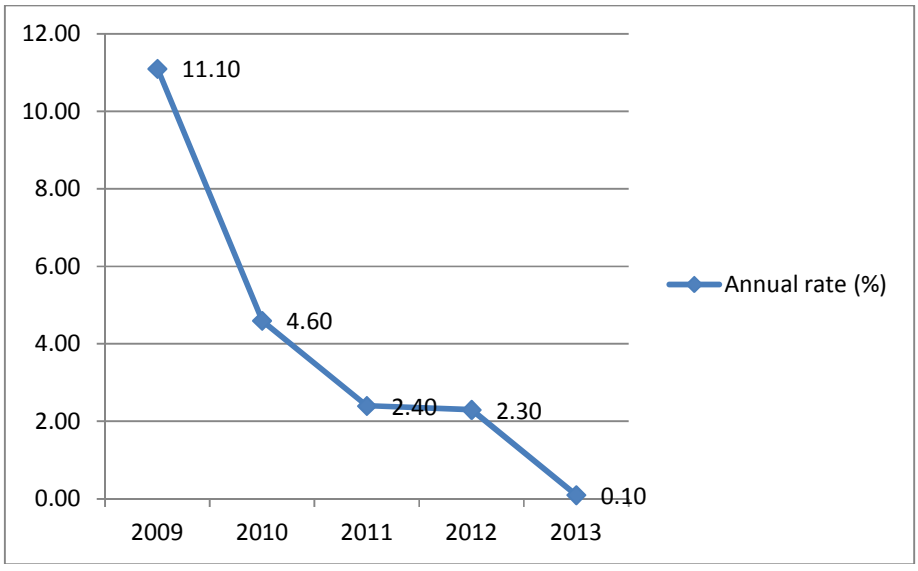
The structure of emigrants by gender indicates that male population has represented a little over 50 % of the total for the entire analysed period.

Diagram 1 - Structure of emigrants, by gender



Although the number of emigrants has increased year after year, the annual increase rate was, however, decreasing. One of the causes was the economic crisis and the unemployment rate also affecting the countries of destination and representing an obstacle in finding a job. Another issue is the fact that free movement of persons inside the EU has increased the workers' mobility, and the reason to change the domicile definitively has decreased significantly and the definitive migration has strengthen.

Diagram 2- Evolution of annual increase rate for the number of immigrants



As it can be noticed, the long term (12 months and more) migration has a higher share, compared to the short term migration (6 - 12 months) - Table 2.

Table 2 - Structure of emigrants, by the presence in the household, 2007 – 2012

	2007	2008	2009	2010	2011	2012
Absent for 6 - 12 months	8.0	4.3	7.8	19.6	21.2	24.7
Absent for more than 12 months	92.0	95.7	92.2	80.4	78.8	75.3

Source: AMIGO, 2012

As regards the structure of the emigrants for 6 - 12 months, by gender, as regards the participation in the economic activity, it indicates that the share of active population ranged between 78.3 % in 2009 and 88.7 % in 2011.

Table 3 - Structure of emigrants (6 - 12 months) according to the participation in the economic activity, by gender, 2007 – 2012

		2007	2008	2009	2010	2011	2012
Active population	**Total**	**81.9**	**81.5**	**78.3**	**85.8**	**88.7**	**88.0**
	Male	61.2	67.4	66.6	65.6	60.4	62.9
	Female	24.538.8	32.6	33.5	34.4	39.6	37.1
Inactive population	**Total**	**18.1**	**18.5**	**21.7**	**14.2**	**11.3**	**12.0**
	Male	45.1	50.7	47.9	51.9	62.5	64.2
	Female	54.9	49.3	52.1	48.1	37.5	35.8

Source: AMIGO, 2012

As regards the structure of the emigrants by age, it is noted that the highest share is of those between 25 and 29 years, followed by those of 30 - 34 years and by those of 35 - 39 years, meaning the active population (table 4).

Diagram 3 - Structure of emigrants by age categories, 2007 – 2012

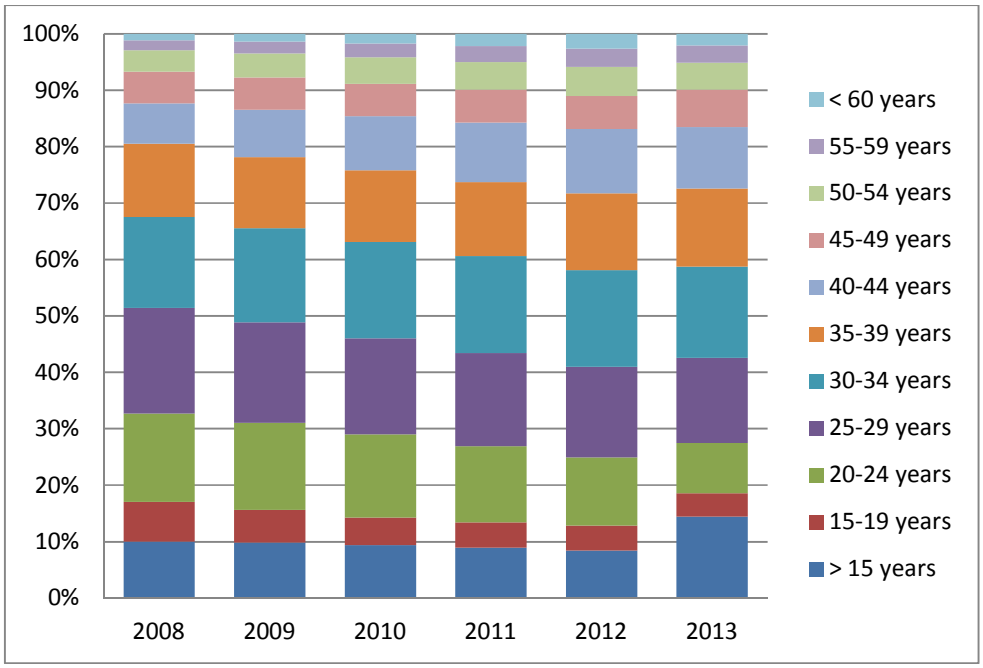


Table 4 - Structure of emigrants by age categories

	2008	2009	2010	2011	2012	2013
Total	**1,922,805**	**2,135,691**	**2,234,155**	**2,288,531**	**2,341,263**	**2,344,183**
> 15 years	193,188	210,608	208,870	203,844	198,075	338,874
15-19 years	134,381	123,060	110,854	103,480	102,996	96,728
20-24 years	301,696	330,252	328,348	309,334	283,380	208,193
25-29 years	359,595	379,433	380,482	377,780	375,133	354,192
30-34 years	308,984	356,349	381,021	392,938	401,346	378,659
35-39 years	250,966	268,361	283,291	298,926	317,787	324,892
40-44 years	136,657	180,768	214,724	241,658	267,516	255,432
45-49 years	108,163	121,711	128,761	133,407	137,208	154,832
50-54 years	73,032	90,843	104,389	112,435	120,251	112,400
55-59 years	33,687	44,327	54,350	65,365	76,656	72,094
< 60 years	22,456	29,979	39,065	49,364	60,915	47,889

By analysing the distribution of the Romanian emigrants in 2013, according to the INS data, we have found that in 2013, 46 % of them were in Italy, 34 % in Spain, 7 % in Germany, 4 % in the Great Britain, 3 % in Hungary and 6 % in other countries.

In 2008, the distribution of immigrants shows that the largest share was in Italy – 38 %, 33 % in Spain, 5 % in Germany, 3 % in Hungary and 17 % in other countries.

Eurostat data show that the standard of living of the main states that were chosen by the Romanian emigrants is higher than the one in the country of origin, but the economies of the respective states have had lower performances in the last years. In Spain, for example, in 2013, the unemployment rate increased to 26.4 %.

The migration is influenced by the level of GDP and of the economic growth (Mărcuță A. Et al, 2014). Thus, in the main countries of destination, in 2012, in Spain, the GDP level was of EUR 22,300/capita, and in 2013, the economic growth was of -1.3 % of GDP. In Italy, GDP was of EUR 25,700/capita, and the economic growth, -1.9 %, and in Germany, GDP was of EUR 32,600/capita, and the economic growth, 0.4 %. In Romania, even if the economic growth was of 2.2 %, the GDP was only EUR 6,500/capita. Hence, in Romania, GDP/capita is 50 % of the EU average, while in Spain, it reaches 96 % of the European average, and in Germany, 123 % of the European average.

In the main countries of destination of the Romanian emigrants, in 2013, the unemployment rate was of 26.4 % in Spain, 12.2 % in Italy and 5.3 % in Germany. In the same year, in Romania, the unemployment rate was of 7.3 %.

The fact that the Romanian emigrants leave the country in search of higher incomes is also demonstrated by the annual net incomes in these countries that were of EUR 26,485 in Germany, EUR 19,359 in Italy and EUR 16,818 in Spain, while in Romania, it was of only EUR 3,606.

The effects of migration on the labour market of the countries of destination are indicated by their influence on the wages, unemployment rate and participation. The same effects also exist in the countries of origin. The departure of workforce abroad may have a favourable effect on the economy, in case that there is a high rate of unemployment and, by leaving abroad, its pressure on the labour market and the budget of social charges decreases. As regards Romania, the effect of migration on the unemployment cannot be quantified because the number of migrants in the statistical data is assimilated in the non-participation rate.

The migratory phenomenon influences the labour market, in a positive or negative way. Thus, when returning home, the migrants have a lower participation in the labour market due to the savings they have and that provide income sources for a certain period of time.

The saved amounts of money are not intended to the development of enterprises, because the returning home phenomenon is sometimes more complicated than migration, and they have to readapt to the economic system or to adapt to jobs offering lower wages, in depopulated areas. Depopulation and

ageing population are other features related to the migratory phenomenon. If they have to choose between the low wages offered in the country and the higher wages abroad, the returned home migrants prefer to leave abroad again or to use their savings or the money sent by relatives abroad.

Another issue is connected to the loss of human capital, even if it is only temporary (Soare E. et al.). As regards the situation of highly educated migrants, their loss is almost in all cases for good. This is way an important issue is the one connected to the education.

The decision to migrate is influenced by the level of education obtained in the home country. Sometimes, the migration itself is related to education or to the obtaining of some professional qualifications abroad. The general level of education may increase and generate long-term positive externalities for the education system, because the remittances may have a positive effect on the education of the children left home.

However, emigration does not have only negative effects on the economy of a country, it also has positive effects, such as the financial transfers from the migrants (remittances), the economic potential of the migrants who invest in businesses when they return home, the increased interest in education in view of finding better job offers.

The remittances may be defined as sums of money forwarded to the country of origin. They increase the incomes of the country from external sources, resulting in the increase of the standard of living of those receiving them, in the development of local economy by increasing the consumption and investments and by reducing the Government's pressure for implementing economic and social reforms.

The studies indicate that the largest share of remittances (80 %) is used for the basic consumption of the families and a rather small share is used for investments in human capital (education, health, nutrition). Another share (5-10 %) is used to buy land, residences etc., being seen often as assets by the emigrants. The rest is used for social and cultural events, for paying debts, for savings. In general, a very small part of these remittances is used to create productive activities. There is no consensus yet as regards the contribution of remittances to the economic growth and the creation of new jobs.

The negative effects of remittances are represented by the increase of inequalities at the level of community, the decrease of the intention to be employed in productive activities on the domestic market, the dependence upon remittances, the inflationary pressure, because the excessive demand of land and residences leads to the artificial increase of their price and, last but not least, the existence of brain drain phenomenon and the migration of trained workers. The remittances do not counterbalance the losses and they distribute investment flows to individual objectives, not local or society objectives.

Because the migration has an impact on the welfare of the entire society, it represents an important factor in designing a policy in this field, that needs the designing of some important aspects regarding the consequences of migration on the labour market, adaptation and integration of migrants to the host-countries. The countries of origin have few instruments in influencing the intention of migrants and they are not directly connected to the migration, but to the credibility of reforms in other fields. The attempts of the state to limit or influence directly the migration decisions will usually have adverse effects.

Migration is a reaction to the inefficiency of demographic and educational policies as regards the demands of the business environment, even if the discrimination and disadvantages compared to the local population are maintained, because the relative advantages compared to the conditions of the labour market of the country of origin always remain strongly positive. Thus, the migration of trained personnel remains an opportunity for the areas of destination and a net loss for the countries of origin.

For the country of destination, the effects are mainly positive and are connected to the fact that migration contributes to the diminishing of the deficit in number and structure of the workforce, for highly qualified professions, strictly specialised workforce or for low qualified or unskilled jobs in connection to which the domestic workforce has reserves. For these jobs, the related costs are much lower.

Because of the migratory phenomenon, the process of population ageing and the stress on the labour market or the budget are diminished, taking into account the fact that immigrants are net contributors to the local budget with their taxes.

The business environments are always positively impacted by the cost advantages and the supplementary consumption generated by mobile workers who remain mobile for a longer period of time.

On the other hand, there are also a series of negative effects connected to the reaction of community to the immigrants who are seen as a social threat due to the problems related to social integration, acceptance of customs and cultural tradition, development in a multicultural environment, due to the social pressure generated by the illegal immigration and the social behaviours related to some categories of populations that are permanently moving. In the same time, the labour market is affected if employers use illegal employment and allow such categories of workers.

Conclusions

One of the reasons of the migration of young Romanians was the weak connection between the education market and the business environment that leaves an important segment of graduates, especially of higher education institutions, outside the labour market.

On the other hand, the poor performance of the labour market institutions and of the local authorities in attracting and employment of the workforce, as employees or entrepreneurs, contributes to the increase of the migratory phenomenon**.**

Even if the largest share of remittances is spent on consumption of goods and services by the family that is left home, there is, however, a multiplied effect of consumption by stimulating the offer and reducing the risk of poverty, with all its effects of driving the social security and assistance system.

Nevertheless, the advantages offered by remittances are only short-term safety valves, strongly connected to the duration of mobility and not enough to compensate the medium and long-term demand for qualified workforce of the Romanian economy.

The loss of human capital is accompanied by the failure to recover the public investments in the education and training of emigrants. Indirectly, the loss of human capital due to the long term or definitive mobility results in lowering the quality of the active workforce on the market.

Abstract

This paper is aimed to analyse the relation between the earnings and the labour costs during the period of 2010-2014 and the way in which the economic crisis has influenced these indicators. The statistical research of the labour cost offers data on which the analysis of its evolution, of its components, as well as of the correlation between these components is based, thus offering the necessary elements for the calculation of the net and gross size, per hour and per month, of the earnings per category of activities of the national economy, type of property, legal type, categories of employees, gender, development region etc.

Keywords: *economic crisis, earnings cost, labour costs,*

Introduction

The structure and evolution of the labour cost and earnings are important elements of the labour market, indicating, on the one hand, the workforce offer, and, on the other hand, the workforce demand.

Workforce represents a cost that includes not only remunerations and wages paid to the employees, but also the non-wage costs (social contributions payable by the employer, plus the costs of training, recruiting, occupational clothing and labour taxes, considered as labour costs minus subsidies). Currently, in Romania, the social contributions amount for more than 30 % of the total labour costs, representing quite a high pressure on the small and medium-sized enterprises.

Material and methods

In this paper were used research methods as: analysis, bibliographical research and statistic research as well as other methods and procedures that allowed revealing the essence of the investigated problem.

Results and discussions

Economic crisis has had a negative impact both on employment and on population' incomes, the most affected being the low and middle-income segments of population. The first effects on incomes have been seen in 2008, and, the next year, the consequences on the economic growth.

In Romania, incomes from labour taxes relative to GDP are much lower than the EU average, but relative to labour income, they are rather high. This shows the high tax burden existent in Romania as regards the labour taxes.

Taking into account the statistical data published periodically by the National Institute of Statistics, and data supplied by specialised European institutions, we have studied the trend of labour costs during the period of economic crisis. The labour tax wedge is given by the percentage of all reductions, social contributions and taxes borne by the employee and the employer in the total labour cost.

The trend of tax burden on the labour cost from 2008 to 2015 indicates that starting with 2008, the tax ratio on the labour cost has increased, and the employees have started to avoid the increase of workload. This is explained by the "low wage trap". The implementation of the flat tax rate starting with 2005 and the lack of indexation of the personal exemption, provided for in the Tax Code for the low and middle wage earners, or the ones with dependents led to the increase of tax burden on the labour cost.

Following an increase in 2009 of the tax burden of 3 percentage points, the growth was constant, being of 43.1 % in 2009, 43 % in 2010 and 2011, 43.5 % in 2012.

In 2013, the tax burden for the high earners was low, because the tax on personal income was fixed, and the social security contributions were capped, but, in comparison, the tax burden remained high for the lower income earners. The decrease of social security contributions with 5 percentage points at all levels, starting with October 1, 2014, has diminished the labour tax wedge for singles, for example, from 42.3 % to 40 %. On the medium to long term, the social security contributions have had a positive impact on the economy and labour market due to the diminishing of labour force costs. Because the diminishing of labour tax wedge was not aimed at the low and middle-income earners, it led to a significant loss of incomes.

Another issue is the high level of hidden earnings on the one hand, and of undeclared employment, on the other. This is explained by the gap between the high tax wedge on labour and the implicit diminished rate of labour taxation. In 2012, according to a Report of the European Commission (Study to quantify and analyse the VAT Gap in the EU-27), approximately 1.57 million persons worked without a legal employment contract, and this had a negative impact not only on tax incomes, but also on the work productivity, labour standards and investments in human capital.

According to the same report, in 2013, the amount of tax avoidance resulted from the undeclared employment and the informal sector was of 3.2 % of GDP. It was a result of the uncollected social security contributions and income taxes.

In addition to the high level of taxation, the number of its components is also high, in Romania, there are ten individually applied taxes, starting with the income tax, social security contributions, health insurances, unemployment fund, applied separately for the employee and the employer, and ending with the contribution to the outstanding claim fund, fund for the occupational risks and accidents, contribution to the leave of absence and indemnities in relation with the health insurances (FNUASS).

In order to analyse the relation between the labour cost and the earnings, we will start with the workforce and the average number of employees existent in Romania.

In 2007 the average number of employees was 4885,3 thousand employees, an increase of up to 5046,3 thousand employees in 2008, followed by a strong decline until 2010. Thus, during the period 2010-2014, the average number of employees had a relatively increasing trend, except 2011, when the average number of employees was of 4348.7 thousand persons. The workforce also had an increasing trend, from 4.581 thousand employees in 2010, to 4.900 employees (Diagram 1).

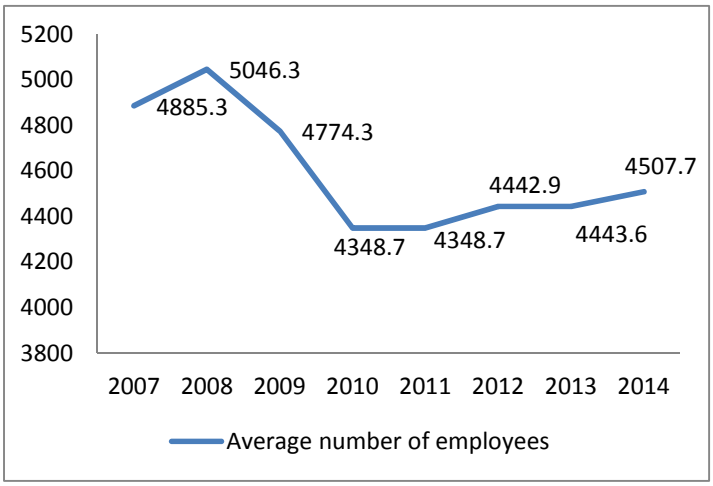

Diagram 1 - The evolution of the average number and of the number of employees

Also labor cost is analyzed and compared to earnings. Thus in 2007 the monthly average gross earnings was of Lei 949,5, in 2008 and 2009 with an increase of 13,5%, respectively 14,5%. In 2010, the monthly average gross earnings was of Lei 1,902, with an increase of 4.1 % in 2012 (Lei 1,980), of 4.2 % in 2013 (Lei 2,063), of 4.8 % in 2013 (Lei 2,163) and of 7.6 % in 2015 (Lei 2,328). To this financial effort, other costs that are borne by employers are added, reaching monthly average expenses of Lei 2,477/employee in 2010, Lei 2,569/employee in 2011, Lei 2,675/employee in 2012, Lei 2,813/employee in 2013 and Lei 2,988/employee in 2014.

In 2010, the real wage index, as the ratio between the net wage index and the consumer price index for the population was of 123.6 % compared to 1990 and with 4.7 % higher than in 2009. In 2011, it increased with 2.3 % compared to the previous year, in 2012, the increase was of 1.2 %, in 2013 of 0.9 %, and in 2014 of 7.8 % in each case, compared to the previous year.

The evolution of the average gross and net earnings per business activity highlights that in 2010, women earned, in average, Lei 221 less than men, the highest differences being in the field of services (+33 %), insurances and financial intermediations (+32.3 %) or in services (+31.2 %). At the territorial level, the monthly average earnings were below average in 37 of the 41 counties plus the Municipality of Bucharest.

In 2011, the earnings of women were with Lei 250 lower than of men, and at territorial level, in 36 counties, the average net earnings were below the average per economy.

In 2012, men earned Lei 215 more than women, and at territorial level, 35 counties had monthly average earnings below the average per economy.

This trend has maintained in 2013 and 2014 also, when the earnings of men were with Lei 176 and Lei 178 respectively higher than of women.

At territorial level, the monthly average earnings were below the earnings per economy in 36 counties, in 2013 and in 2014.

The following are among the factors influencing the labour cost: labour productivity, GDP distribution to the employees, level of unemployment, level of training etc (Mărcuță L. et al., 2013).

By analysing the labour productivity, we found that, in 2013, for Romania, it is the second lowest in EU. During the period 2010-2014, the productivity/employed person has decreased with 0.5 % in 2010, and then, it has increased with 1.9 %, 5.7 % and 4 % in the following years, then it has decreased with 2.8 % in 2014, showing a low level of adjusting capacity of the economy.

Table 1 - Labour productivity in 2013

Country	Productivity/ hour (EUR)	Country	Productivity/ hour (EUR)	Country	Productivity/ hour (EUR)
Austria	31.4	Germany	39.7	Poland	10.6
Belgium	38.0	Greece	20.2	Portugal	17.1
Bulgaria	4.9	Ireland	29.0	Romania	5.6

Czech Republic	13.1	Italy	28.1	Slovakia	13.2
Cyprus	17.2	Latvia	8.4	Slovenia	21.4
Croatia	N/A	Lithuania	10.6	Spain	21.1
Denmark	53.5	Luxembourg	35.7	Sweden	45.5
Estonia	11.1	Malta	N/A	Hungary	11.5
Finland	31.4	Great Britain	30.9		
France	34.3	the Netherlands	33.2		

Source: Eurostat

The labour productivity per hour in Romania is of approximately 9.5 times lower than in Denmark, 8 times lower than in Belgium and Germany, 6 times lower than in Italy, 4 times lower than in Greece and 2 times lower than in Lithuania. If we take into account that the general level of prices in Romania is approximately 2 times lower than is EU, then the productivity per hour adjusted with the Purchasing Power Parity is 4.75 times lower than in Denmark, 4 times lower than in Belgium and Germany etc. Another issue is connected to the low added value included in the Romanian products and services. If we analyse the labour cost per hour in 2013, according to Eurostat data, we find out that, in Romania, it is of EUR 4.6/hour, figure that places us on the last but one place in Europe, the variance between us and the countries with the highest cost per hour being higher than 1 to 10.

Table 2 - Labour cost per hour in 2013

Country	Labour cost per hour (EUR)	Country	Labour cost per hour (EUR)	Country	Labour cost per hour (EUR)
Austria	31.4	Germany	31.3	Poland	7.6
Belgium	38.0	Greece	13.6	Portugal	11.6
Bulgaria	3.7	Ireland	29.0	Romania	4.6
Czech Republic	10.3	Italy	28.1	Slovakia	8.5
Cyprus	17.2	Latvia	6.3	Slovenia	14.6
Croatia	8.8	Lithuania	6.2	Spain	21.1
Denmark	38.4	Luxembourg	35.7	Sweden	40.1
Estonia	9.0	Malta	12.8	Hungary	7.4
Finland	31.4	Great Britain	20.9		
France	34.3	the Netherlands	33.2		

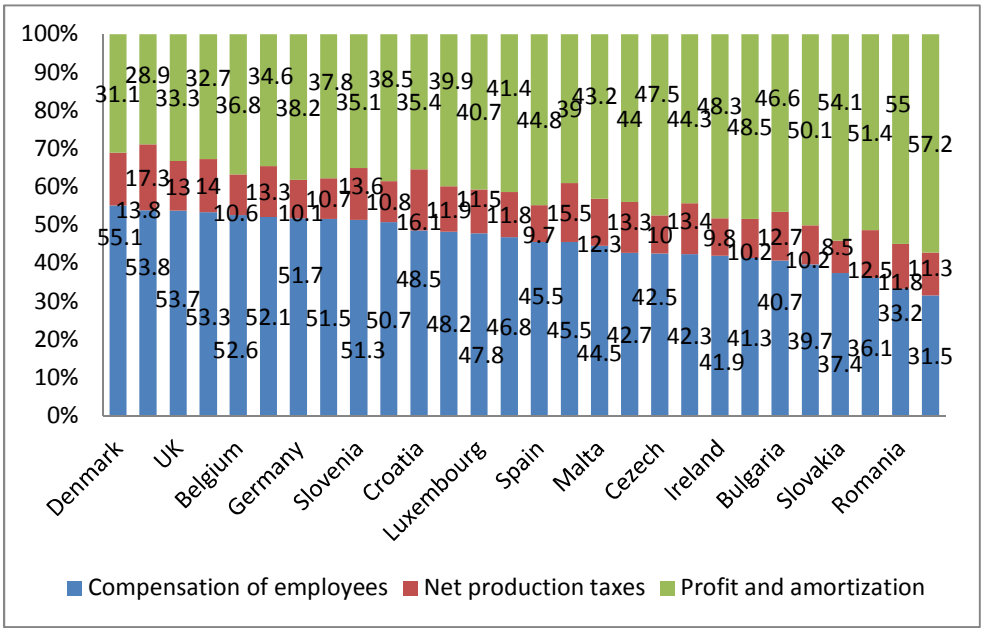
Source: Eurostat

In 2014, the average labour cost per hour was of EUR 24.6 in the European Union and EUR 29.2 for the Eurozone. However, there are large differences between the member states, where costs are ranging from EUR 3.8/hour to EUR 40.3/hour. Romania has the last but one place, with only EUR 4.2 per worked hour (out of which, 22.9 % are non-wage costs).

Another element that influences the labour cost is represented by the way in which the GDP is distributed between the employees, employers and the state.

Eurostat data for 2013 indicate that in Romania there is an imbalance between the remuneration of employees, because they receive approximately 33 % of GDP, the employers receive 55 % of GDP, its aim being to cover the depreciation and the profit, and 12 % of GDP for the state. This imbalance might be a result of the low level of training of the workforce, the lack of interest of the employers for their employees, and their weak reaction towards their own interests.

Diagram 2 - Components of GDP



Source: Eurostat

The labour cost is also influenced by the relation between the wages and the unemployment rate and they are inverse proportional (Dobrescu Monica et al.). In Romania, where, on January 1, 2015, the unemployment rate was of 6.5 %, this relation does not exist, because the wages and the rate of unemployment are lower in comparison with the European average, and this can be justified by the high level of workforce migration, the weak social protection system, the over-employment in agriculture.

Another aspect that was emphasized earlier is related to the training level of the employees, because the level of wages and the level of labour cost both depend on it.

In Romania, the most of the low-trained workers are in the agricultural sector, and in construction sector. The workers of the service and trade sector have completed university and postgraduate studies. Thus, the share of low level of education is of 9 % in trade, 10 % in the extractive industry, 11 % in services, 17 % in the manufacturing industry, 22 % in constructions and 28 % in agriculture. The employers with an average level of training represent 67 % in the manufacturing industry, 66 % in the extractive industry, 62 % in trade, 59 % in services, 58 % in constructions and 50 % in agriculture. The employees with a high level of training represent 30 % of those working in services, 29 % in trade, 25 % in the extractive industry, 22 % in agriculture and 16 % in the manufacturing industry.

According to the INS data, in 2013, the average gross earnings were of Lei 1,945, the lowest wage being registered in agriculture, of Lei 1,675 and the highest, in the extractive industry, of Lei 4,227.

As regards the system for changing the wages, it is influenced by the inflation rate. Compared to prices, wages are more rigid in Romania.

Conclusions

The frequent amendment of the tax policy is one of the causes affecting the business environment.

The relative high tax burden in Romania, especially for low-income earners, undermines the supply and demand on the formal labour market, resulting in low participation rates and a significant shadow economy.

The tax treatment of implementing the flat rate has led to the inhibition of the intention to work more for the low-income earners.

Although it was known from the beginning that the diminishing of social security contributions will have a negative impact on the budget, it was considered that the impact would be positive on the business environment. It was considered that the measure would lead to the increase of the funds at the disposal of the employer, sources that could be used to create new jobs, contributing to the increase of the basis for social contribution.

It was also considered that this measure could lead to the increase of the number of taxpayers and, implicitly, to the efficiency of the contributions/beneficiary ratio, as well as of the taxable incomes, meaning, the increase of incomes to which the contribution is applied. However, the tax easing measures did not have the anticipated effect.

It is noted that the elasticities of labour market supply and demand continue to be relatively high for the low skilled, low-income earners. This is why by reducing the tax burden for this category, it could lead to an increase of the employment rate.

Another important issue to be considered is the fight against the undeclared employment. In addition, solutions have to be found to diminish the tax burden borne by the low and middle-income earners, but without affecting the budget.

Managing Attitudes of Consumers towards Brands and Quality

Lenka Ližbetinová, Faculty of Corporate Strategy, The Institute of Technology and Business in Českе Budejovice, Czech Republic, e-mail: lizbetinova@mail.vstecb.cz
Dagmar Weberová, Faculty of Multimedia Communications, Tomas Bata University in Zlin, Czech Republic, e-mail: weberova@fmk.utb.cz

Abstract

The purpose of this article is to evaluate attitudes and preferences of consumers in the Czech Republic in relation to quality perception of domestic and foreign brands. Results presented are compared to the outcomes of a similar research study carried out in the Slovak Republic. In this article, partial outcomes of primary research focused on attitudes and preferences of Czech consumers in relation to attributes, such as price, quality, product information, and preferences of domestic products, are presented. This primary research was conducted in the Czech Republic in the period of October and November of 2014 and respondents were approached via an electronic questionnaire and personal interviews. This article presents a more detailed with respect to specific structures of consumers in the Czech Republic.

Keywords: consumer behavior, consumer, brand, brand perception, quality

Introduction

Research questions asked in the questionnaires in both countries, the Czech Republic and Slovakia, reflect the assumption that perception of brand quality and brand trust affect consumer behavior (Nadanyiova, 2015) including consumers' purchasing decisions (Mooij, 2011; Vysekalova et. al, 2011; Kampf et. al, 2012). Research results presented in this article confirm that perceived quality makes the brand look special in the eyes of consumers and lead to brand trust and thus increased brand loyalty. Moreover, delivering exceptional quality across products and individual attributes brings a price premium (Aaker & McLoughlin, 2010, p162). As research outcomes suggest, consumers are willing to pay more for branded products (Krizanova et. al, 2013; Slaba, 2015) of higher quality regardless of their origin. Thus, it is recommended that businesses consider (Rebetak & Farkasova, 2013) the perceived quality as one of the most important parts of their business strategy (Aaker et. al, 2007). Furthermore, businesses should realize that it is consumers who define superiority. So it is vital for businesses to understand what drives perceived quality and actively to manage it (Aaker & McLoughlin, 2010, p163). Moreover, it is recommended that businesses focus on visible aspects affecting quality perception (Aaker & McLoughlin, 2010; Stopka et. al, 2015). Otherwise a decrease in quality brings disappointment for consumers. A higher level of quality perception means higher potential for disappointment if consumers' expectations are not met. Building trust creates expectations (Aaker & McLoughlin, 2010, p167), therefore it is important for businesses to minimize the number of problems (Potkany & Stachova, 2015) associated with a particular brand (Schiffman & Kanuk, 2004) and if any arise, businesses should do their best to eliminate them as quickly as possible (ALraja & Chikhi, 2015; Vetrakova et. al, 2013)

Materials and Methods

The main objective of this article is to evaluate attitudes and consumer preferences in relation to brand perception and trust in domestic and foreign brands. Research results are compared with the data available from a similar research conducted in Slovakia (Smolkova, 2013; Smolkova et al., 2013). Findings presented in this article are partly based on the outcomes of primary research carried out in the Czech Republic in the period of October and November of 2014 by the Department of Marketing Communications, Faculty of Multimedia Communications, Tomas Bata University in Zlin. This research study was focused on brand perception among Czech consumers according to selected criteria, such as price, quality, information, and domestic brands. The sample of respondents was comprised of residents of the Czech Republic older than 18 years. The sample was determined on the

basis of quota sampling based on the principle of division of the same proportion of selected properties of the elements according to population (Kotler and Keller, 2006; Aaker et. al, 2007). Quotas based on age, gender, income, size of municipality and districts in the Czech Republics (Starchon & Weberová, 2014) "were determined for the purpose of this research. Quota distribution of these socio-demographic data is based on parameters obtained from the Czech Statistical Office (2014). The sample included 1028 respondents. Respondents were approached via an electronic questionnaire and personal interviews. Within this research, respondents were asked a total of 38 questions, of which the first three were open and investigated the spontaneous brand awareness and associations with the Czech brands. Then a series of 28 Likert scales followed – these were designed to detect consumer preferences and their attitudes towards domestic and foreign brands in terms of their price, quality, information, and preferences. Scales had a form of statements and respondents had the opportunity to express themselves in the range of five points*: I fully agree – I partly agree – I do not know – I partly disagree – I fully disagree*. In addition, three open questions were asked to investigate spontaneous brand awareness of consumers.

Research evaluation followed on the basis of respondents' division (seven remaining questions in the questionnaire) – they were classified according to socio-demographic characteristics, such as age, education, gender, territorial jurisdiction, municipality size, net household income, and the number of employed household members. The obtained data were processed by using statistical characteristics and all the chi-square tests were calculated with a confidence level of 0.05 and the accepted tolerance of 3% accuracy. In this paper, partial outcomes of the research dealing with attitudes and perception of Czech consumers toward quality of branded products are presented. Data were processed with the help of the SPSS Statistics Program by IBM (IBM Corporation, 2015). The results presented in this paper are obtained by cross-analysis in the form of a weighted arithmetic mean of statements.

Table 1: Structure of the Czech and Slovak respondents according to selected criteria

Criteria	Czech Republic	Slovak Republic
Gender	**Number**	**Number**
Male	505	504
Female	523	518
Age	**Number**	**Number**
18-29 years old	208	278
30 - 39 years old	273	228
40 - 49 years old	185	189
50- 59 years old	160	245
over 60 years old	130	87
Education	**Number**	**Number**
Primary education	113	75
Secondary education without GCSE	284	61
Secondary education with GCSE	423	497
Higher education	208	371
Municipality size	**Number**	**Number**
up to 2 thousand inhabitants	160	169
2 - 5 thousand inhabitants	103	138
5 - 10 thousand inhabitants	71	73
10 - 20 thousand inhabitants	95	119
20 - 50 thousand inhabitants	169	152
50 -100 thousand inhabitants	142	191
over 100 thousand inhabitants	286	187

Note: GCSE means General Certificate of Secondary Education.

Then, these partial outcomes are compared with the results of primary research carried out by Smolkova et al at the Faculty of management, Comenius University in Bratislava in 2013. Data were gathered in the period of January to April 2013 by means of personal interviews and an online questionnaire available on the Internet. This sample consisted of 1067 respondents. Quota

distribution of socio-demographic data – residents older than 16 years old - is based on parameters obtained from the Slovak Statistical Office. The questionnaire in Slovakia had a similar form as in the Czech Republic thus it is possible to compare the results obtained from both research studies. The Slovak questionnaire consisted of 35 questions, 27 of them were focused on consumer attitudes towards brands according to specific attributes, and three open questions investigated spontaneous brand awareness. Only five questions dealt with respondents' socio-demographic characteristics. Data from research conducted in Slovakia were processed in the Statgraphic Program (Statpoint Technologies, 2015) and in the R statistical software (The R Core Team, 2015).

Table 1 provides an overview of the samples of both primary researches conducted in the Czech Republic and Slovakia. Based on the structure of respondents, this paper investigated consumer attitudes with respect to the trust and quality of the brands. Therefore, within primary research, the following six statements were used:

- „Czech products are of higher quality."
- „I trust Czech brands over foreign brands."
- „I have better experience with foreign brands."
- „I buy foreign brands because of higher quality."
- „I trust foreign brands more."
- „ Foreign brands are of higher quality."

Respondents' attitudes towards the statements are evaluated by assigning numerical values to particular answers in the rating scale as follows: *I fully disagree* (-2), *I partly disagree* (-1), *I do not know* (0), *I partly agree* (1), and *I fully agree* (2). In order to provide a clear overview of respondents' attitudes, results are processed with the help of cross tables in the form of a weighted arithmetic mean of respondents' answers.

Results and discussion

This article presents partial outcomes of primary research concentrating on evaluating consumer attitudes and preferences in the Czech Republic in relation to quality perception and trust in domestic and foreign brands. These results are obtained by evaluating six questions with the help of a weighted arithmetic mean of respondents' answers in the following rating scale: *I fully disagree* (-2), *I partly disagree* (-1), *I do not know* (0), *I partly agree* (1), and *I fully agree* (2). The results based on specific attributes (gender, age, educational attainment, municipality size, and net household income) of the sample will be presented.

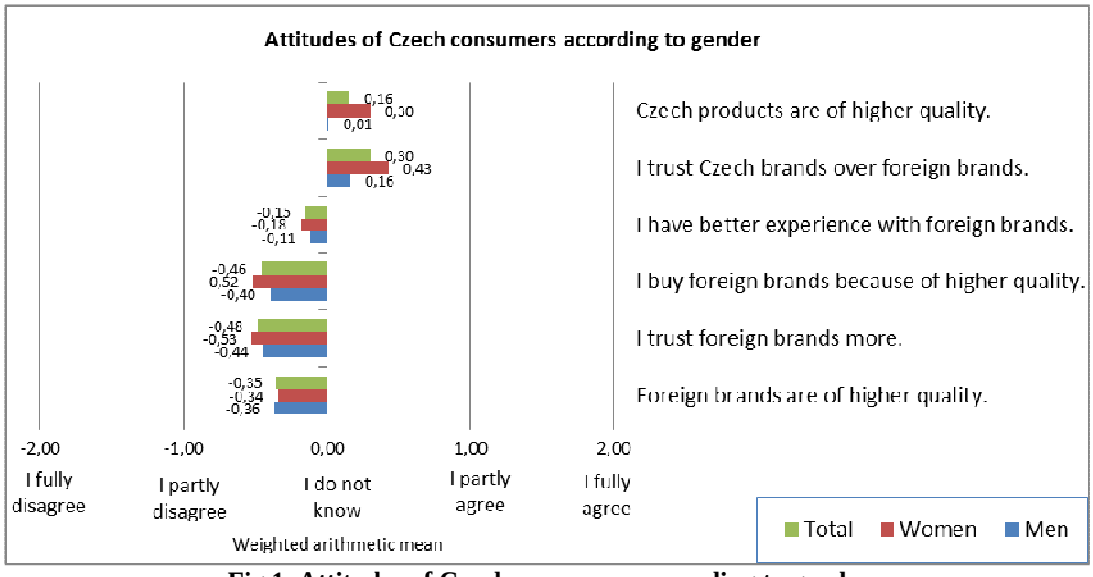

Fig 1. Attitudes of Czech consumers according to gender

Source: Own (based on research)

Figure 1 presents the attitudes of respondents according to gender. The results show that women, compared to men, tend to trust Czech brands (51.82%), and many of them, almost one half, thinks that Czech products are of higher quality (46.27%). Men show a rather indecisive attitude toward this fact (32.87% agree, and 35.44% of them do not know).

Furthermore, 42.77% of men trust more Czech brands than foreign ones – this is less by 9.04% than at women. The attitude of female respondents is clearly reflected also in reverse formulated statements favoring foreign brands. More than a half of women do not buy foreign brands because of higher quality (56.21%) nor because they would trust them (55.07%). In terms of quality and trust in foreign brands, men more or less share the position of women.

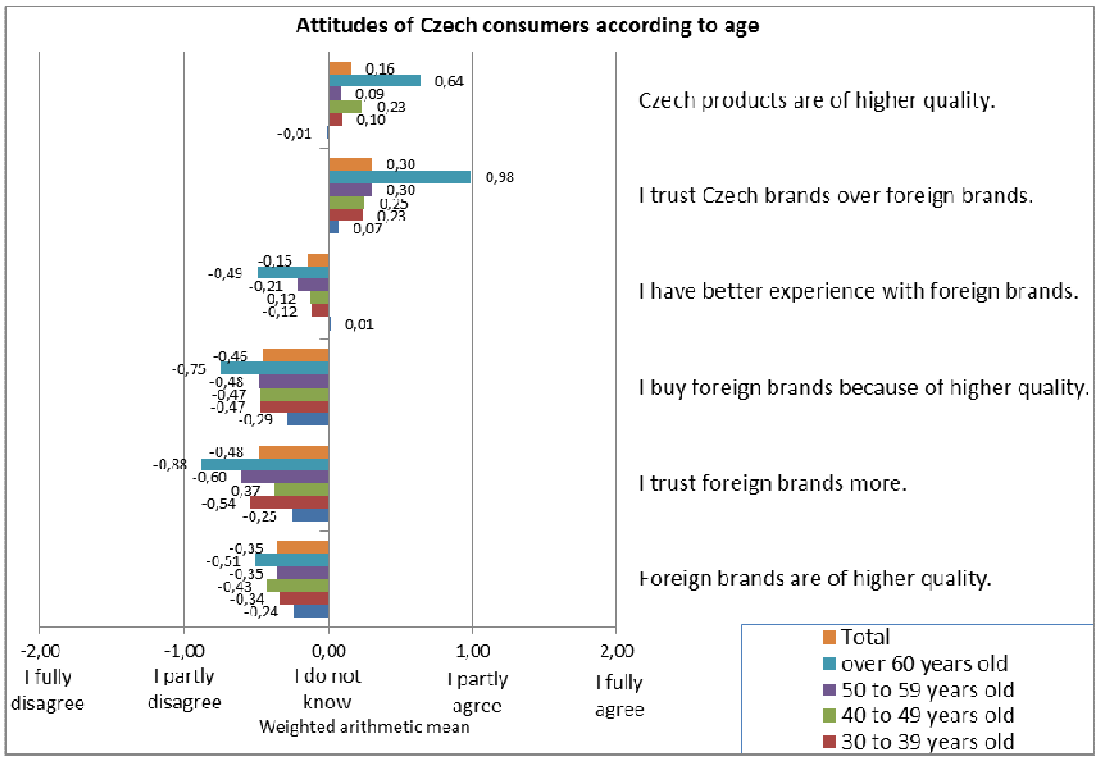

Fig 2. Attitudes of Czech consumers according to age

Source: Own (based on research)

Respondents' attitudes to quality and trust in brands based on the age structure of Czech consumers are presented in Figure 2. In general, it can be stated that higher consumer trust in domestic brands over foreign ones is seen with increasing age. This tendency can be observed in a much stronger way at consumers over 60 years (70.77%) than at other age categories (respondents in the youngest age category up to 29 years trust domestic brands less by 35.05%). Trust in Czech brands tends to be rather indecisive at young generation (35.71% of these respondents trust them and 34.29% of them do not know). Quality perception of Czech products provided similar results – only 28.92% of these respondents consider them for quality products and 43.21% of them do not know. But at the same time, they rather disagree (45%) with the fact that they would buy foreign products because of higher quality and better experience with them (30%). Other older generations also fail to show clear attitudes towards quality perception of Czech brands. Research results suggest that even if consumers do not show a clear view on higher quality of Czech products, compared to the quality of foreign brands, a clearer view on trust can be observed. All in all, it can be stated that Czech consumers do not buy foreign brands because of their higher quality. If consumers buy them, there are also other reasons why they do so.

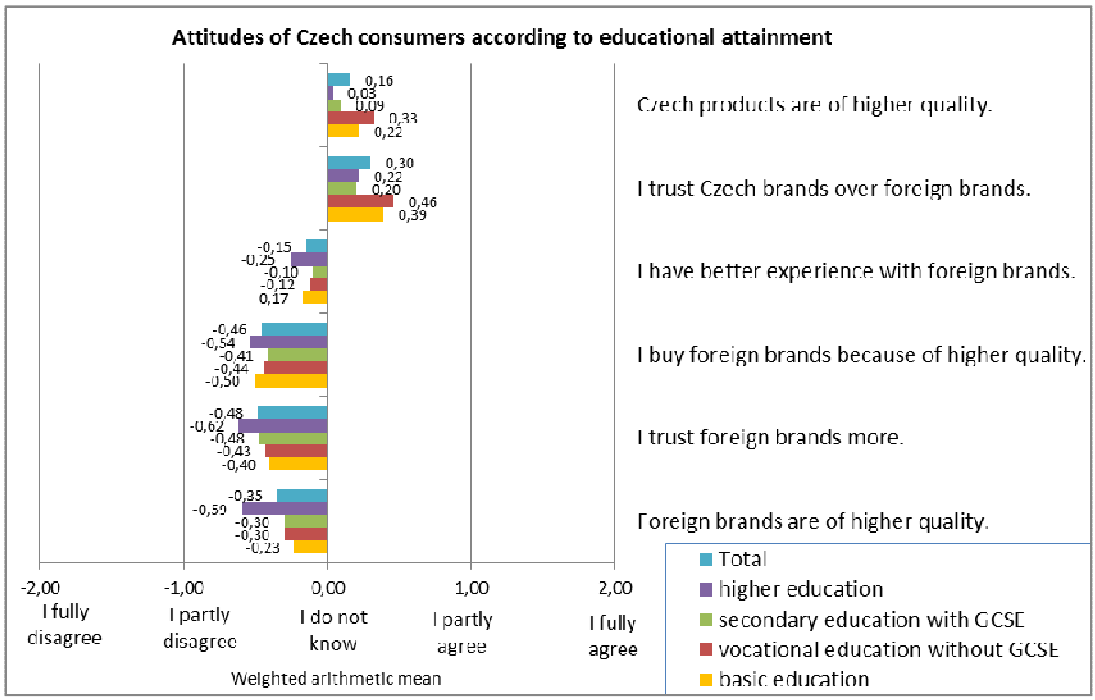

Fig 3. Attitudes of Czech consumers according to educational attainment

Source: Own (based on research)

Note: GCSE means General Certificate of Secondary Education.

Within this research study, respondents were divided, based on their level of their educational attainment, into four groups – basic education, secondary vocational education without GCSE, secondary education with GCSE, and higher education. Results based on the level of respondents' educational attainment are shown in Figure 3. Based on the weighted arithmetic mean, Czech respondents with secondary vocational education without GCSE (52.47%) and with basic education (50.44%) show the highest level of trust in domestic brands. Consumers with a higher level of educational attainment (44.03% with secondary education with GCSE and 47.6% with higher education) tend to trust more domestic brands than foreign brands but their attitude toward higher quality of Czech products compared to foreign ones is rather indecisive (36.77% of them agree, 31.85% of them do not know and 31.38% of them disagree). At the same time, consumers with higher education (57.21%) most disagree with the statement that foreign products would be of higher quality and they (59.62%) trust them less than other groups of respondents.

The group of consumers with a lower level of educational attainment has more positive attitude toward the quality of Czech products (39.82% with basic education, and 46.13% with secondary vocational education without GCSE). At the same time these respondents do not think foreign brands would be of higher quality (35.4% with basic education and 42.25% with secondary vocational education without GCSE) but this opinion is shared by fewer respondents (the difference makes 21.81%) than by respondents with higher education.

According to their net household income, Czech consumers are divided into 12 categories. Their attitudes to the statements are shown in Figure 4. A vast majority (61.11%) in the category of respondents with net household income less than CZK 9,000 shows trust in Czech brands and considers them of higher quality compered to foreign products. The same tendency can be observed in the attitude of disagreement – 77.8% of these respondents disagree with the statement that foreign brands would be of higher quality. Many of them (61.11%) lack trust in foreign brands and they do not buy these products for other reasons including the fact that they do not think these products would be of higher quality (64.7%). In general, trust in Czech brands with increasing income of respondents decreases, the income category of 57 to 69 thousand crowns demonstrates a very ambiguous attitude while the category of respondents with net household income over 69 thousand crowns holds rather

negative attitude – 48.65% do not consider Czech products of higher quality and state that have even a better experience with foreign brands (51.35%).

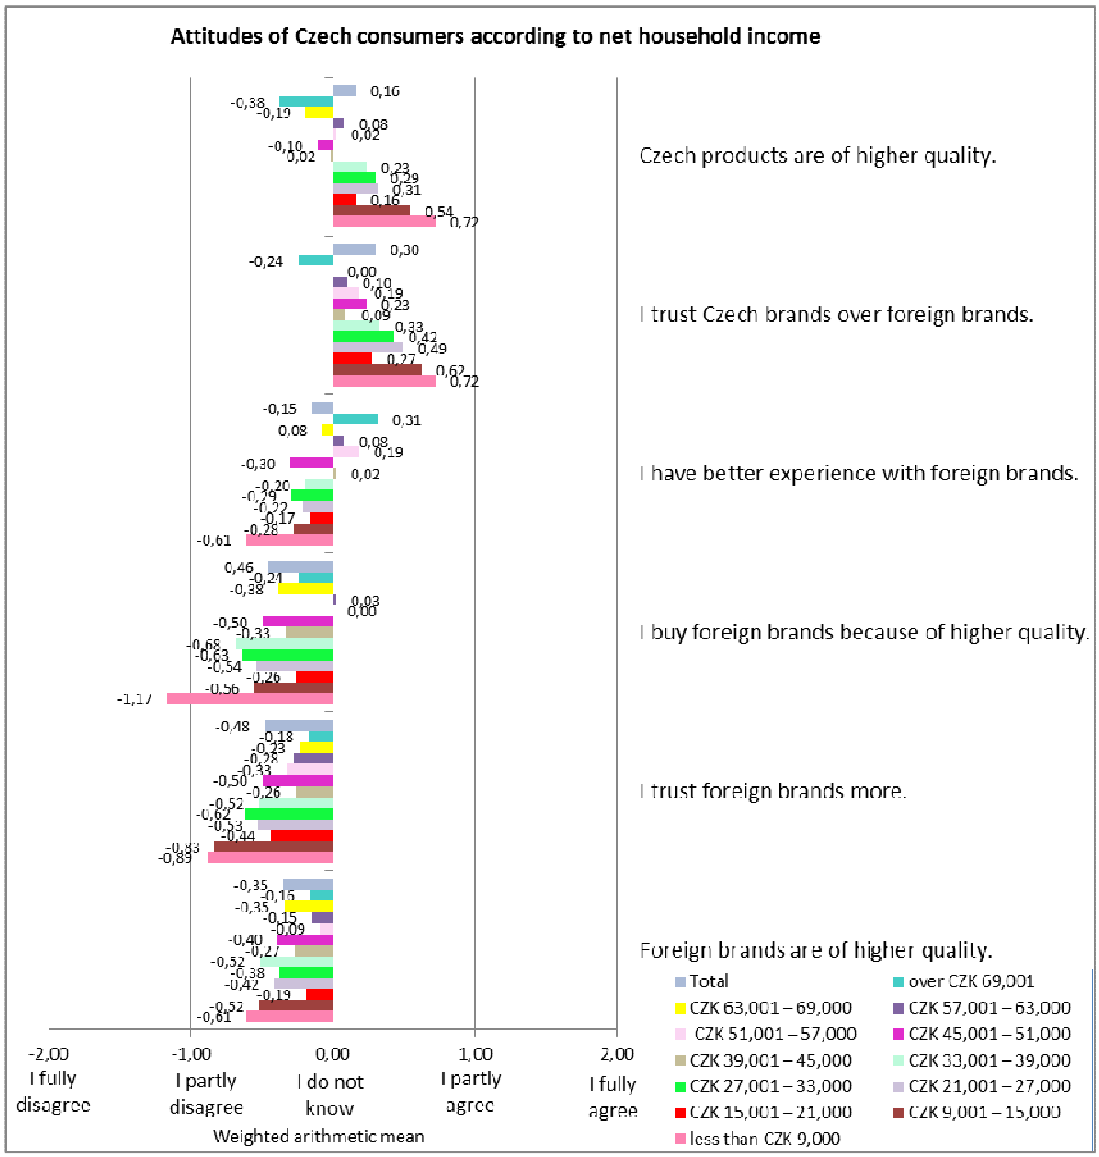

Fig 4. Attitudes of Czech consumers towards brands according to price and net household income

Source: Own (based on research)

On the other side, households with incomes up to CZK 39,000 perceive Czech products as of higher quality (44.85%) and trust them more than foreign brands (51.82%). All in all, consumers hold negative attitude to the statements claiming that foreign brands are of higher quality and that they would trust foreign brands more.

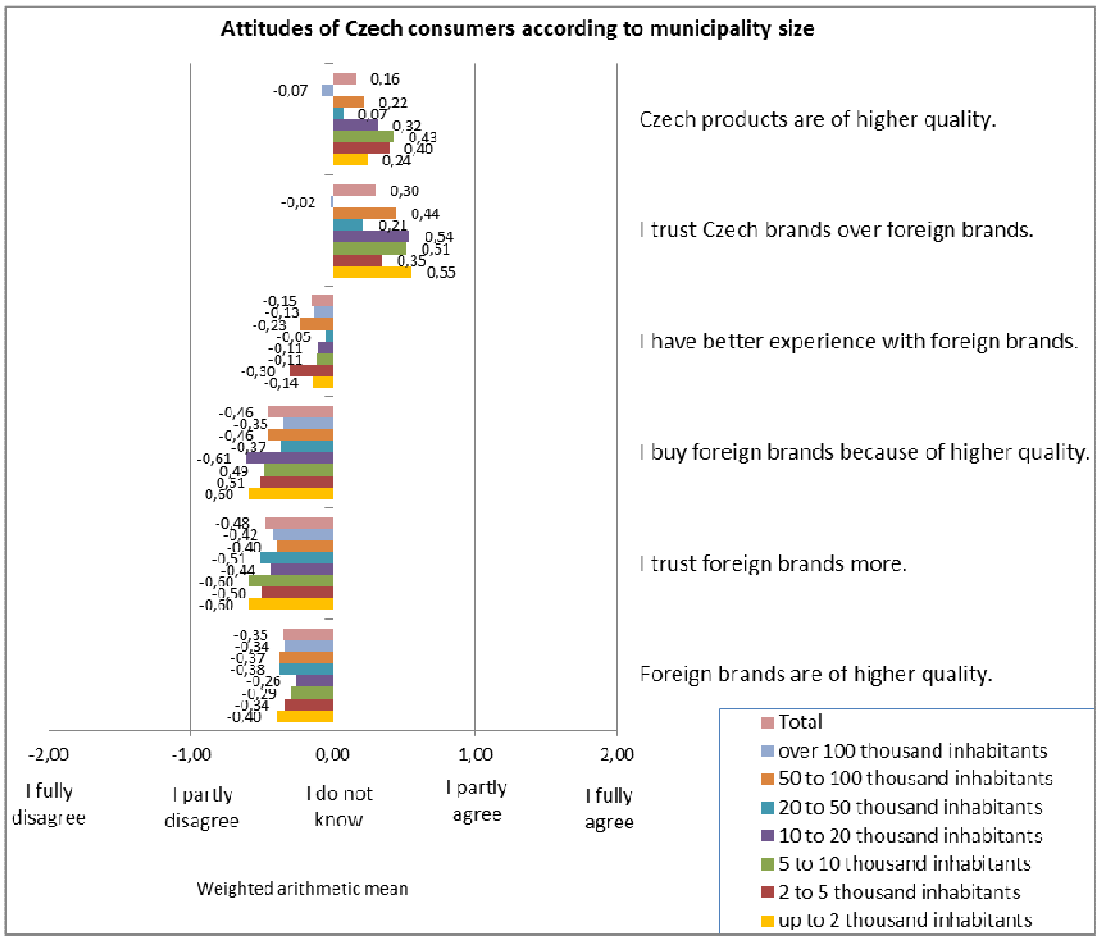

Figure 5: Attitudes of Czech consumers towards brands and price according to the municipality size

Source: Own (based on research)

Evaluating attitudes of respondents according to their municipality size (Figure 5) it can be stated that the bigger the municipalities size the less trust in Czech products. The only exception is the category of 50 to 100 thousand inhabitants where a higher level of trust in Czech brands (52.11%) can be observed, and these respondents also consider them to be of higher quality (45.07%) compared to municipalities of 20 to 50 thousand inhabitants (38.43%). In general, it can be said that Czech consumers, without a significant difference, do not hold higher trust in foreign brands (54.28% of all categories) and they do not consider them of higher quality (45.23%). More hesitant or even negative attitude can be seen when evaluating the statement that respondents have better experience with foreign brands – only respondents living in municipalities of 2 to 5 thousand inhabitants (40.37%) and 50 to 100 thousand inhabitants strongly disagree with this statement.

Conclusion

Looking at the results presented in this paper it can be summarized that Czech products and brands are in terms of quality not perceived negatively and Czech consumers rather trust them. This tendency is much higher among women, older age categories, the categories with lower educational attainment, at households with lower net income, and among respondents from smaller municipalities. On the other side, foreign brands are not perceived as better or of higher quality. In general, Czech consumers do not have any better experience with them, and they have no greater trust in them. Respondents in households with net income over CZK 69,001 have, concerning trust (35.14% trust them, and 21.62% do not know) and quality of foreign brands (32.43% agree with the statement that foreign brands are of higher quality, and 43.24% disagree with it), ambiguous attitude,

and 51.35% of them claim to have better experience, 48.65% do not consider domestic products to be of higher quality, and 42.3% have no trust in them. Looking at the results based on age it can be stated that the youngest generation of 18 to 29 years old shows the lowest inclination to quality and trust in Czech brands. These results are compared with a similar research carried out in the Slovak Republic (see Figure 6).

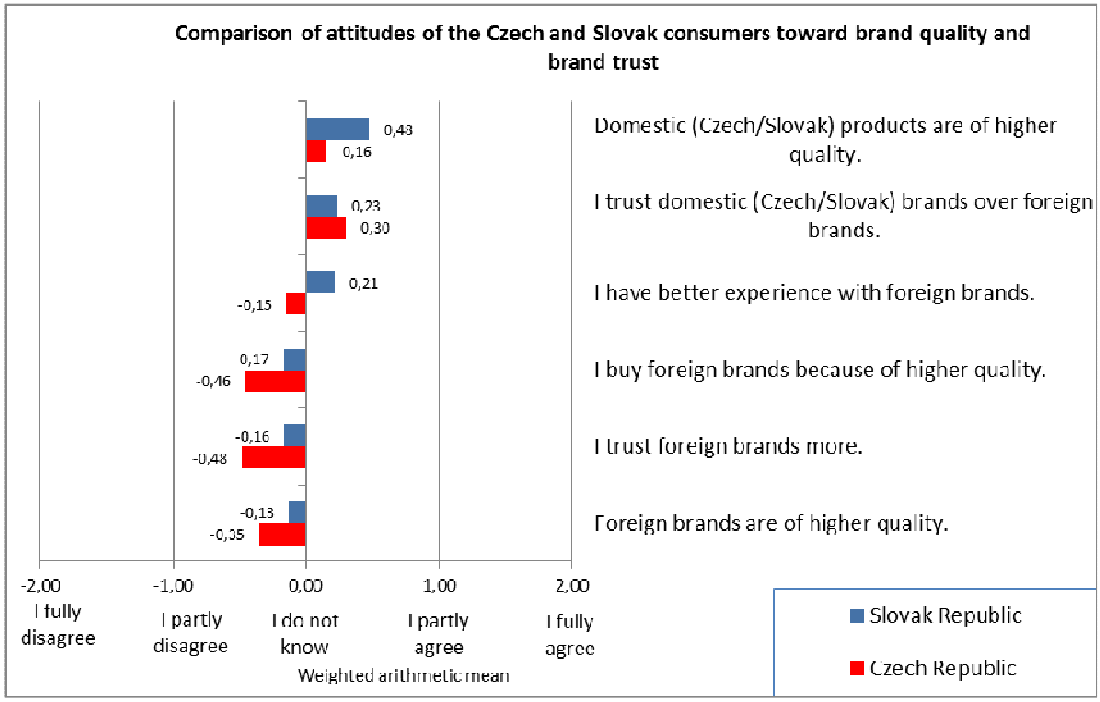

Fig 6. Comparison of attitudes of the Czech and Slovak consumers toward quality and trust in brands

Source: Own (based on research)

The comparison of the results shows that 55.45% of Slovak respondents trust the quality of domestic products (while 32% do not know). This is more by 15.76% than among the Czech consumers (39.69% while 27.78% do not know). On the other side, the question of trust in domestic products was slightly more positive among Czech consumers; approximately 47% of respondents in both countries agreed with the statement, only 28.5% of the Czech respondents disagreed with the statement – this is less by 2.01% compared to the Slovak consumers. It can be stated that in both countries, domestic products are, in terms of trust and quality, perceived in a rather positive way.

Investigating respondents' experience with foreign brands, different attitudes can be observed between the Czech and Slovak respondents. Slovak consumers claim to have rather better experience with foreign brands (42.29%) while the attitude of Czech consumers (29.6% agree) is more negative (39.1% disagree and 31.32% do not know) because in Slovakia 29.6% disagree which is less by 9.5%. This attitude is confirmed by the results of the statement that foreign brands are of higher quality, consumers trust them more and buy them because they are of higher quality. Slovak consumers show a slightly negative attitude (46.7% disagree with the statement) compared to 48.5% of Czech respondents who disagree with the statement too.

The results of the research focused on the attitudes of Czech and Slovak consumers are, in terms of trust and quality, encouraging and positive for domestic producers placing their products in the domestic market. Consumer behavior is naturally affected by other attributes, of which price can be considered as the most influential. This was investigated within both research surveys and it was found out that in both countries, respondents do not focus only on the cheapest products and this tendency is stronger with increasing net household income - this fact can be seen as an opportunity (Farkasova, 2013; Jurikova, 2014) for companies to attract consumers (Lorincova & Balazova, 2014) with different qualities but the price.

Abstract

Understanding and implementing supply chain management is a necessary condition to remain competitive in the global competition and improve profitability and consequently of supply chain management (SCM), which is a relatively recent thinking in the management literature. Although many researches highlight increasingly the importance of SCM, as well as scholarly materials remain scattered and disjointed. Moreover, none of research has been directed towards a systematic identification of the core initiatives and constructs involved in SCM. This research is both descriptive and applied research focuses on manufacturing companies of Romanian is considered as a statistical population. Thus, the purpose of this study is to develop a research framework that improves understanding of SCM and stimulates and facilitates researchers to undertake both theoretical and empirical investigation on the critical constructs of SCM. Additionally, this research attempts to study the impact of supply chain practices on competitive position of small and medium sized manufacturing enterprises. The result has showed that there is a relationship between supply chain management practices and competitive advantage in small and medium sized manufacturing enterprises. Also results showed that efforts in: (1) improving customer satisfaction, (2) Strategic supplier partnership (SSP), (3) Customer Relationship (4) Level & Quality of information sharing has significant impact on the competitive position of the company..

Keywords: supply chain management, competitive advantage , small and medium sized manufacturing..

Introduction

The history of small manufacturing has been one of the most controversial stories in economic development in the world. The role of small manufacturing in an economy has frequently been undermined and even misinterpreted. In the past, small businesses were believed to impede economic growth by attracting scarce resources from their larger counterparts (Audretsch, et al., 2000) small manufacturing contribute significantly to both local and global economic development. They are a crucial business sector for all nations' economies. In developed countries, SMEs typically account for 60 per cent of employment, and the figure is even higher in developing countries.(Audretsch et al., 2000).

From the onset of the industrial revolution until the 1960s large corporations capitalizing on economies of scale were considered as the deriving force of growth and development (US Small Business Administration (SBA), 1998). The emergence of computer-based technology in production, administration and logistics and information has, however, reduced the role of economies of scale in many sectors. Many studies (Loveman and Sengenberger, 1991; Acs and Audretch, 1993) have shown a shift in industry structure away from greater concentration and centralization towards less concentration and decentralization – a shift towards an increased role for small firms. This was mainly due to changes in production technology, supply chain managment, just in time, in consumer demand, labor supply, the pursuit of flexibility and efficiency. These factors, in turn, led to the restructuring and downsizing of large enterprises and the entry of new firms. More and more evidence became available to indicate that economic activity moved away from large firms to small, predominantly young firms. (Brock and Evans 1989) .

In today's dynamic business environment coupled with globalization, the survival of Small to Medium Size Enterprises (SMEs) will be determined by their ability to produce more, at a lower cost, in less time, and with few defects. Essentially, these enterprises need to improve their efficiency. SMEs form the largest group of manufacturing firms which provide manufacturing and support services to Large Enterprises (LEs) in many supply chains. (Meehan, J., and Muir, L., 2008) .

During the last fifteen years the Romanian manufacturing sector has evolved and modernised considerably . There has been a growth in the implementation of new technologies (such as SCM -lean manufacturing- and EDI -Electronic Data Interchange-) and the development of new manufacturing formats (such as automotive and metal industry and construction) . The most important characteristics of this sector are: its high concentration level (in 2000, the first five groups had a market share of 50% approximately) . In the context of an economy in full uptrend, the Romanian industry is characterized by an effervescence generated on one side of the infusion of foreign capital attracted by cheap labor force, well qualified, low costs, Romanians experience and on the other hand by the Romanian automotive manufacturers. (A . Hagiu 2012) .

The highly competitive environment of the small manufacturing sector has made companies look for a competitive advantage. Logistics management has the potential to assist the organisation in the achievement of both a cost / productivity advantage and a value advantage (Christopher, 1998) . But, the logistics perspective that considers the company itself without considering its supply chain members is not sufficient . To gain this competitive advantage, there is the need to adopt the Supply Chain Management (SCM) approach and consider the supply chain as a whole.

Compete in global markets will expand in 1990s, challenges creates related to product and service offerings to the right place, at the right time, with the lowest cost and highest quality. Studies showed that approach of supply chain management (SCM) used increasingly as an opportunity to achieve these goals by many organizations . Therefore, understanding and implementation of supply chain management is a necessary condition to remain competitive in the global competition and improving profitability (Moslem, G et al 2013) and improving organizational performance . However, the understanding why and how SCM affects firm performance . Business enterprises are responsible to manage a network of upstream firms (suppliers) that provide inputs and a network of downstream firms (customers) that deliver products and services . Serving the right customers, finding the right suppliers, and fostering trust with the right partners have a great impact on current as well as future business performances. Traditional organizational boundaries are a topic of the past . Business enterprises today focus on their Supply Chain Management (SCM) in order to improve product quality and lead time due to stiff competition from global markets and increased levels of customer's expectation (Murali, S. and George ,J 2008). SCM can play a proactive role in enhancing competitiveness and profitability (Tracey, Lim, & Vonderembse, 2005). By addressing supply chain management practices that can lead responsiveness, will make better

understanding the scope and activities related with supply chain management practices that create enhanced level of supply chain responsiveness in today's competitive market place.

Therefore the purpose of this studies is to empirically test a framework identifying the relationships among SCM practices, competitive advantage and organizational performance . SCM is defined as a process for designing, developing, optimizing, and managing the internal and external components of the supply system in a manner that is consistent with the overall objectives and strategies (Spekman, Spear, & Kamauff, 2002). Globalization and worldwide competition are facilitating innovation in the ways businesses are being conducted and thus changing business strategies. SCM practices are defined as the set of activities undertaken by an organization to promote effective management of its supply chain . In this paper , we have identified the SCM practices that impact the competitive position of a company. The practices of SCM are proposed to be a multi-dimensional concept, including the downstream and upstream sides of the supply chain. The ultimate goal of SCM is to integrate various members of the supply chain in a seamless manner to achieve a high level of customer satisfaction, and thus a longterm competitive advantage (Ebrahim, K. and Mahmoud, R 2014) .

The aim of this study is to find out the effect of supply chain management practices such as strategic supplier partnership, customer relationship, information sharing and supply chain responsiveness of on competitive advantage . So that main question is: Which has practices of supply chain management (SCM) impact the competitive advantage in Romanian manufacturing companies? This study also assess the effect of supply chain integration in term of internal firm integration, integration with suppliers and integration with customer on firm competitive advantage. The paper is organized as follows: relevant literature is reviewed and synthesized first to develop a conceptual model , followed by research methodology . The results are then presented along with discussions. of the study and highlight research motivation.

2. Literature review

2.1. The Supply Chain management

.

The concept of "supply chain" is well established in the literature and is generally referred to as the alignment of firms that bring products or services to market (Mihai, F and Irina, A ,2013) . Supply chain management (SCM) is a cross-functional interenterprise system that uses information technology to help support and manage the links between some of a company's key business processes and those of its suppliers, customers, and business partners. The goal of SCM is to create a fast, efficient, and low-cost network of business relationships, or supply chain, to get a company's products from concept to market.
SCM coordinates and integrates all of these activities into a seamless process to server as an opportunity and profit for customers .It links all of the stakeholders in the chain including parties within an organization and the external partners including suppliers, carriers, third party companies, and information systems providers (Habib, M.M. 2011) . In this research, the variables are : strategic supplier partnership , customer relationship , level of information sharing , information sharing quality and internal lean

2.2. SCM practices.

SMC practices have been defined as a set of activities undertaken in an organization to promote effective management of its supply chain (Li et al., 2006) . SCM practices involve suppliers in strategic and operational decision making, encouraging information sharing and searching for new ways to integrate upstream activities.It also involves developing customer contacts through the use of customer feedback to integrate the downstream activities and delivering orders directly to customers at point of use. To effectively achieve these goals, it is necessary to locate closer to the market, help suppliers and vendors

develop JIT capability, create a compatible information platform and create SCM teams for quality and operational efficiency (Diana, B. 2011). Supply chain practices are related to supply and materials management issues, operations, information technology and sharing (ICT) and customer service (Tan, 2002) . Supply chain practice also includes: technology, cost competitiveness, inventory management and external regulation (McMullan, 1996). All those have to be managed effectively to realize supply chain's strategic position which allows competitive advantage.

Some identify the concept SCM as including agreed vision and goals, information sharing, risk and award sharing, cooperation, process integration, long-term relationship and agreed supply chain leadership. Thus the literature portrays SCM practices from a variety of different perspectives with a common goal of ultimately improving organizational performance. SCM practice depends on business strategy and collaboration in the organization, plan and execution, logistic performance and information technology and its implementation in the organization and including five distinctive dimensions: strategic supplier partnership, customer relationship, level of information sharing, quality of information sharing and postponement (Li et al., 2006). Researchers have identified a number of constructs pertaining to SCM, which is shown in

Table 1: SCM constructs identified by the researchers

SCM constructs	**Researchers**
Strategic supplier partnership	Gunasekaran et al., 2001; Tan et al., 2002; Li et ,2005
Customer relationship	Aggarwal, 1997; Tan et al., 2002; Li et al., 2005; 2006
Level of information sharing	Li & Lin, 2006; Li et al., 2005; 2006
Quality of information sharing	Li & Lin, 2006; Li et al., 2005; 2006
Internal lean practices	Handfield & Nichols, 1999; Mason-Jones & Towill, 1997

2.2.1 Strategic supplier partnership (SSP)

Nowadays organizations have found that if they worked together , total interest income is over the situation that they work without coordinating with related agencies (Moslem, G 2013). This term is defined as a long term strategic coalition of two or more firms in a supply chain to facilitate joint effort and collaboration in one or more core value creating activities such as research, product development, manufacturing, marketing, sales, and distribution, with the objective of increasing benefits to all partners by reducing total cost of acquisition, possession, and disposal of goods and services (Maheshwari et al., 2006, Li et al., 2006) .

Strategic partnership with suppliers enables organizations to work more effectively with a few important suppliers who are willing to share responsibility for the success of the products. Strategic partnership emphasizes direct relationship and long-term and encourages mutual planning and efforts to resolve problem. Supplier organizations can work together more closely and eliminate useless time and effort. Effective partnerships with suppliers can be critical factor to guide supply chain management (Li et.al,

2oo6, p110). The main objective of strategic partnerships with suppliers is increasing the functional capability desired supplier (Rosenzweig , 2003).

2.2.2 Customer Relationship

Comprises the entire array of practices that are employed for the purpose of managing customer complaints, building long-term relationships with customers, and improving customer satisfaction ,according to Claycomb Tan et al. . CRM is a strategic approach concerned with creating improved shareholder value through the development of appropriate relationships with key customers and customer segments. CRM unites the potential of relationship marketing strategies and IT [information technology] to create profitable, long-term relationships with customers and other key stakeholders. Tan et al. consider customer relationship management as an important component of SCM practices. The growth of mass customization and personalized service is leading to an era in which relationship management with customers is becoming crucial for corporate survival. Close customer relationship allows an organization to differentiate its product from competitors, sustain customer loyalty, and dramatically extend the value it provides to its customers. Good relationships with supply chain members, including customers, are needed for successful implementation of SCM programs. Customer relationship goals can be mentioned as follows (Niknia, 2007, p53) :

- Identifying new business opportunities
- Reduce missed opportunities
- Reducing customer defection
- creating customer loyalty
- Improve customer service
- Improve organization appearance
- Reduce costs

2.2.3. Level & Quality of information sharing

Information sharing has two aspects: quantity and quality and is a key ingredient for any SCM system. Both aspects are important for the practices of SCM and have been treated as independent constructs in the past SCM studies.(Ebrahim and Mahmoud, 2014). Many researchers have suggested that the key to the seamless supply chain is making available undistorted and up-to-date marketing data at every node within the supply chain . By taking the data available and sharing it with other parties within the supply chain, an organization can speed up the information flow in the supply chain, improve the efficiency and effectiveness of the supply chain, and respond to customer changing needs quicker. Therefore, information can be used as a source of competitive advantage.

The information in a supply chain can be classified in different ways e.g. : strategic or tactical; logistical; or pertaining to consumers (Mentzer 2004). Lee and Whang (2000) discuss various types of shared information and their potential benefits . Information sharing leads to high levels of supply chain integration(Choi,. T.Y,.and Hartley,.J.L. 1996) by enabling organizations to make dependable delivery and introduce products to the market quickly. Quality information sharing contributes positively to customer satisfaction and partnership quality . Information sharing impacts the supply chain performance in terms of both total cost and service level (Suhong, L. and Binshan 2006). According to Lin et al. , the higher level of information sharing is associated with the lower total cost, the higher order fulfillment rate and the shorter order cycle time. While information sharing is important, the significance of its impact on SCM depends on what information is shared, when and how it is shared, and with whom. Literature is replete with example of the dysfunctional effects of inaccurate/delayed information, as information moves along the supply chain (Lee,.H.and Billington,.C.1992). Divergent interests and opportunistic behavior of supply chain partners, and informational asymmetries across supply chain affect the quality of information(Lee, J. and. Kim,Y 2000). It has been suggested that organizations will deliberately distort information that can potentially reach not only their competitors, but also their own suppliers and

customers. It appears that there is a built in reluctance within organizations to give away more than minimal information since information disclosure is perceived as a loss of power. and companies fear that information may leak to potential rivals. Given these predispositions, ensuring the quality of the shared information becomes a critical aspect of effective SCM (Zeinab,. S 2014). Organizations need to view their information as a strategic asset and ensure that it flows with minimum delay and distortion and companies fear that information may leak to potential rivals.

2.2.4. Internal Lean Practices

The term "lean" refers to a production system , which focuses on the elimination of all forms of waste and non-value added activities (Womack et al., 1990). This attitude for the first time in 1950 in Toyota plant by Ohno (Technical Deputy of Factory) was designed and implemented (White, 1993) .
While Internal Lean Practices have enhanced the efficiency of individual organizations, greater benefits can be obtained when considering its implementation in a supply chain context (Hines et al., 2004; Shah and Ward, 2007) . Another supply chain management practices is the use of internal lean practices. Internal lean practices refer to consume less system resources uses with the same speed mass production and offers greater variety to customers. One of the fundamental ideas in internal lean practices is removed surplus (Hassanzadeh & et al, 2010).
There are some studies that have investigated the role of internal lean operations together with external SCM practices (e.g. Tan, 2002; Li et al., 2005, 2006; Wong et al., 2005; Zhou and Benton, 2007). For instance, Li et al. (2005) conceptualized, developed and validated a set of SCM practices, which included ILP, strategic supplier partnership, customer relationship, information sharing, information quality and postponement.
The most famous of internal lean practices can be mentioned timely and lean produce. Production of lean and timely is production system that its aims are to optimize processes and production process by reducing waste and other inefficient factors. This attitude for the first time in 1950 in Toyota plant by Ohno (Technical Deputy of Factory) was designed and implemented (White, 1993, p40) .

2.3. Competitive advantage

Competitive advantage is the extent to which an organization is able to create a defensible position over its competitors . It comprises capabilities that allow an organization to differentiate itself from its competitors and is an outcome of critical management decisions . (Ferry, J. et al 2007) .
In today's global competition environment, facing the rapid technology progress and high customer expectations, companies find it hard to win the competition only depending one's own capacity (Su et al., 2008) . In this situation, the establishment of the supply chain partnership among companies and the coordination of the partners are highly valued.
On the basis of prior literature , are define the following five dimensions for competitive advantage : competitive pricing, premium pricing , value-to-customer quality, dependable delivery, and production innovation (Suhong, L. and Binshan 2006) . Based on the above, the dimensions of the competitive advantage constructs used in this study are price/cost, quality, delivery dependability , product innovation and time to market.

3 . Research

3.1. Research hypotheses

That is why we started to develop a framework of SCM practice , collecting and using knowledge from related literature. The framework developed in this SCM proposed that the practices of SCM has and direct impact on the overall performance of the organization.(Shin, Collier, & Wilson, 2000; Prasad & Tata, 2000) . Practices of SCM are supposed to increase the market share of an organization, return made on investment (Shin, Collier, & Wilson, 2000; Prasad & Tata, 2000) and also help the organization to improve the competitive position in the market (Carr & Person, 1999; Stanely & Wisner, 2001). The

objective of strategic partnership with the supplier is increasing benefits to all partners by reducing total cost of acquisition, possession, and disposal of goods and services (Maheshwari et al., 2006; Li et al., 2006). Relationship with the customer acording to greenberg (2001) below are objectives and strategies for an organization that implement CRM increse revenue and reduction of cost of sales and sales representative retention and increse sales representative productivity. The level of information sharing, related with lowering the total cost, the rapid and higher rate of fulfilling the orders of the customers, and shortening the time of order cycle(Lin, Huang, & Lin, 2002). A recent survey had concluded, organizations that are good in implementation of SCM, hold advantage of 40%-65% in cash-to-cash cycle time on the other organizations and the top organizations are carrying from 50% - 85% than their competitors (Sheridan, 1998) .

Moslem et al (2013) in their study on Khuzestan province's manufacturing companies found that SCM practices have a direct and significant impact on Khuzestan province's manufacturing companies and there is relationship between supply chain management practices and competitive advantage in Khuzestan province's manufacturing companies.

Therefore the following hypothesis are proposed:

- First hypothesis: there is relationship between strategic supplier partnerships (SSP) with competitive advantage in small and medium sized manufacturing enterprises Romanian .
- Second hypothesis: there is relationship between Customer Relationship (CR) with competitive advantage in small and medium sized manufacturing enterprises Romanian.
- Third hypothesis: there is relationship between level of information sharing (LIS) with competitive advantage small and medium sized manufacturing enterprises Romanian
- Fourth hypothesis: there is relationship between internal lean practices (ILP) with competitive advantage in small and medium sized manufacturing enterprises Romanian
- Fifth hypothesis: Small and medium sized manufacturing enterprises Romanian with high levels of SCM practices will have high levels of competitive advantage.

3.2 Research methodology and data collection

Research methodology is developed by (Li et al., 2002), and instruments that measure competitive advantage were adopted from (Diana, B. 2011). The items for these instruments are listed in Appendix . The research population is small and medium sized manufacturing enterprises in Romania and sampling method is stratified random sampling .

The empiric research has been conducted on defined sample of 25 Romanian small and medium sized manufacturing in a period from October 2015 to februarie 2016. The questionnaires have been collected by e-mails. The companies in sample are this list of the manufacturing firms consists of materials of construction, automotive, metal, plastic, rubber and other industry components. The manufacturing firms concerned in this study were ranged from medium to small companies, with more than 10 employees and less then 50 employees . According to SME Corp , medium companies are those with full time workers between 51-250 while large companies have full time workers over 251. The decision made in this study is derived from the studies done by (Lila, 2012).

A majority of the respondents belong to middle and upper management were those from managing directors, manufacturing and/or production managers and executives, and also quality managers and executives. The main inquiry of study was to find out the attitude employees and level of understanding of manufacturers whose production processes related to SMEs manufacturing, located in Timisoara and have average 8.5 years of experience.

In present research, questionnaire was used to survey managers and experts views in small and medium sized manufacturing enterprises in Romania . For validity of questionnaire is used content validity and for

reliability of questionnaire is used Cronbach's alpha coefficient. Cronbach's alpha coefficients for the variables in the questionnaire is obtained higher than 70%, thus questionnaire is reliable
The examinee was able to answer using a 5-point Likert scale between the endpoints : not at all, To a small extent, To a moderate extent, To a considerable extent, complete applicable, demographic data for the respondents is given. For data analysis is used Pearson's correlation coefficient.

The collection of data was completed in februarie 2016, followed by data processing. The final sample included 125 questionnaires. The questionnaire return rate was 80 %

4. Results and Discussion

The empirical research took three months starting from October 2015 until februarie 2016. Collecting data was used from 25 industry firms the data was captured through meticulous survey questionnaires undertaken in various small and medium sized manufacturing enterprises established in Romania whose production processes related to automotive and plastic and metal and construction manufacturing . Responses from participants were collected, coded , and entered into a Microsoft Excel spreadsheet (Microsoft 2010). The data was coded according to the tracking number, the date received, definite, and open-ended answers. 125 respondents were lastly retrieved, 26 each from the management team, engineer or supervising team and operating teams. Result form part I of the survey is as shown in Table (2)

Table 2: table title here

Years of employement	**Total respondents**	**Percentage**
Under 1 year	10	8%
1-2	20	16%
2-5	60	48%
More than 5 years	35	28%
The number of company workers		
From 1-9		12%
From 10-49		32%
From 50-250		56%
Position in the company		
production Management		32%
Administrative		68%
Types of product produced		
Plastic parts		16%
Metal parts		12%
Construction parts		20%
Electronic parts		28%
automotive		24%

The general background of the respondents such as years of employement and the number of company workers and types of product produced are presented in Table (2). Results showed that the respondents were (48%) from workers have a level hold bachelor degree, workers in administrative team (68%), and (48%) workers have 2-5 years of working experiences. The factors studied were the types of produce and firm period. Most of the respondent were from firms which manufacture electronic parts for industries were (28 %). the companies involved in this study medium entreprises are categorised as intermediate was (56%) and (32%) medium companies .
The small and medium enterprises were measured those enterprises whose whole number of workers is less than 250 people, with the following sectors, micro-enterprises (1-9 employees), small enterprises

(10-49 employees), and medium enterprises (50-250employees). The type of definition established, firmly on a single principle the number of people employed in enterprises determined the extention of its use in the current statistics of the European Union.

The mean and standard deviation (SD) of perceptions of respondents about relationship between SCM practice concepts Strategic supplier partnership (SSP), Customer Relationship, Level & Quality of information sharing, Internal Lean Practices and competitive advantage and efficiency are presented in (Table 3).

Table 3 : Means, standard deviations, correlations and reliability of SCM practice, competitive advantage

Perception	Mean	SD	Meaning
Strategic supplier partnership	3.72	0.71	significant
Customer Relationship	3.89	0.67	significant
Level & Quality of information sharing	3.35	0.66	significant
Internal Lean Practices	3.34	0.64	significant

The mean and standard deviation (SD) of perceptions of respondents correlations and reliability of SCM practice, competitive advantage.

According to the obtained results was observed that is a significant correlation coefficient between strategic supplier partnership and competitive advantage, ($p<0.05$) . It shows the positive correlation among these variable. So this is best fit for regression model. Thus research hypothesis is confirmed and there is relationship between strategic supplier partnerships with competitive advantage in small and medium sized manufacturing enterprises Romanian. According to the obtained results was observe that is a significant correlation coefficient between CR and competitive advantage and given the level of significance in this test ($p < 0.05$) , thus research hypothesis is confirmed and there is relationship between CR with competitive advantage in small and medium sized manufacturing enterprises Romanian. According to the obtained results was observed that is a significant correlation coefficient between LIS and competitive advantage. ($p<0.05$). It shows the positive correlation among these variable. So this is best fit for regression model , thus research hypothesis is confirmed and there is relationship between LIS with competitive advantage in small and medium sized manufacturing enterprises Romanian.

According to the obtained results was observed that is a significant correlation coefficient between ILP and competitive advantage, ($p<0.05$). It shows the positive correlation among these variable. So this is best fit for regression model , thus research hypothesis is confirmed and there is relationship between ILP with competitive advantage in small and medium sized manufacturing enterprises Romanian.

5. Conclusions

This study provides an empirical justification for a framework that identifies five key dimensions of SCM practices and describes the relationship between SCM practices and competitive advantage .It looks at 5 investigation queries: (1) strategic partnerships with suppliers can impact on competitive advantage; (2) Customer Relationship has impact on competitive advantage; (3) level of information sharing has an impact on the competitive advantage; (4) internal lean practices affects the competitive advantage ; (5) Small and medium sized manufacturing enterprises Romanian with high levels of SCM practices will have high levels of competitive advantage. Test results indicate that strategic partnerships with suppliers, CR, LI S ,and ILP have an impact on a competitive advantage. This study offers a number of managerial implications. First, by developing and validating a multi-dimensional construct of SCM practices and by exhibiting its value in improving performance of Small and medium sized manufacturing enterprises

Romanian; it provides SCM managers with a useful tool for evaluating the efficiency of their current SCM practices. Second, the analysis of the relationship between SCM practices and competitive advantage indicates that SCM practices might directly influence competitive advantage of SMEs manufacturing Romanian. Third, the findings of this study tend to support the view that implementation of SCM practices has a significant impact on the competitive advantage of SMEs manufacturing in an emerging country. Finally, we find that the small and medium sized manufacturing enterprises Romanian with high levels of SCM practices have high levels of competitive advantage

Abstract

The article presents a method of knowledge representation developed for the construction of a knowledge management system (KMS). The starting point of the research is to analyse the stages and decision problems in the technological preparation of production of selected machine elements. In the system there is a symbolic information processing and therefore it has been assumed that knowledge is going to be expressed with the use of symbols. The way of building the symbolic knowledge representation about the structure, based on the identification of geometric features has been characterized. The construction of the technological symbol in knowledge representation about the structure of the technological process of machine parts has been inserted. Associations between these representations in the form of decision rules, which will be stored in the system knowledge base, have been proved. A diagram of building a framework of knowledge representation and an example of record of the decision rules in the structure of the frame.

Keywords: knowledge representation, knowledge management system (KMS), technological knowledge, decision rules.

Introduction

Modern economy should be based on knowledge, which resources and proper management of these resources are seen as the most important source of enterprise's competitive advantage. This applies not only to organizations where employees intellectual capital is a key resource to be transformed into products such as: expertises, designs, software (Awad, Ghaziri, 2008; Dalkir, 2005; Mertins, Heisig, Vorbeck, 2003). Knowledge is an important resource in the development of manufacturing enterprises, which is the main source of innovation (Baruk, 2006; De la Mothe, Foray, 2001). Knowledge management is understood as a set of actions fitting a proper form and the processes direction taking place in the company's knowledge resources. The strategic goal of knowledge management is the multiplication of intellectual capital and the enlargement of the organization's efficiency. In the case of the knowledge management, key processes are discerned, such as: locating, acquiring, development, distribution, use and preservation of knowledge (Davenport, Probst, 2002; Frappaolo, 2006; Wong, Aspinwall, 2004).

Research carried out on artificial intelligence in the range of processing tools of the knowledge determined the emergence of new opportunities (Negnevitsky, 2002; Rutkowski 2008). Attempts are being made to implement the elements of artificial intelligence in the knowledge management systems, but they are most often aimed at the knowledge codification strategy and its proper storage in the system (Giarratano, Riley, 2005; Madanmohan, 2005). This approach is too general to make knowledge management practitioners proceed directly to implementation. In this regard, one can feel a distinct lack of a strict methodology for applying elements of artificial intelligence in knowledge management systems in manufacturing companies.

The primary purpose of technological production preparation is a choice of the right technological option due to the adopted the decision criteria. A typical task is to analyse the following problem: what operations, in what order and by what technological means must be performed to receive the finished product fulfilling the conditions relating to the net-shape precision, surface quality and minimization of production costs (Chryssolouris, 1992). Technological preparation of production in the enterprise bases on technological expertise. This knowledge includes the collection of information about the production process carried out in the specific realities of the company. Technological knowledge is a dynamic collection, because in the companies there are frequent changes in processes, e.g. production parameters, machinery, tools, etc. (Trajer, Paszek, Iwan, 2012). Knowledge determine the ability of companies to react quickly to the market and constitute an information database to generate new products, technologies and organizational solutions (Knosala, 2002; Paszek, Wittbrodt, 2015).Stages of production preparation require the right knowledge, describing the possible solutions for the decision-making problems. It is required to develop a knowledge representation, thanks to which a computer system for knowledge management in the enterprise may be elaborated.

Analysis of Decision Problems in the Technological Preparation of Production

The elaboration of a knowledge management system in the enterprise starts with an analysis of the production preparation processes of selected machine elements. This analysis results in the determination of decision-making problems, the solution of which requires specific sets of technological knowledge accumulated in the system. Regarding the elaboration of the knowledge analysis involves:

- construction of machine elements, e.g. the type of material, geometric dimensions, surface net-shape precision, surface roughness, heat treatment, surface hardness, kind of electroplating, etc.,
- technological characteristics of the production system, it means the analysis of the production capacity of the considered company, technical tools, tasks to be performed at a given technological position, the cutting tools base and technological hardware, etc.,
- relationships between the element construction and the process structure, it means determination of technological and technical resources that need to be applied to obtain the required characteristics of the element,
- the ability to create new constructional solutions of elements and their respective processes, it means identification of possible sets of the item's distinguished features, which can be obtained in a real production system on particular machines and technological hardware.

Preparing of the knowledge sets is based on a multi-stage structure of the technological process of machine parts. The sequence of distinguished decision steps results from the choice of manufacturing operations, in order to increase the net-shape precision and fit desired properties to the treated objects, until the finished product is achieved. In various stages of the design, partial decision problems were picked out, what allowed to organize them according to assumed knowledge sets. Below, distinguished stages and decision-making problems are highlighted:

- *Stage of blank selection:*
  - determination of the basic material type (e.g. rolled bar, forging),
  - selection of the input material characteristics (e.g. characteristic parameters).
- *Stage of pre-treatment selection:*
  - selection of input operations (e.g. straightening, cutting, initial turning),
  - preparation of basic machining bases,
  - selection of the initial heat treatment.
- *Stage of basic processing selection:*
  - specification of the required basic methods of the element processing (e.g. turning, milling),
  - the division of machining into roughing and shaping,
  - selection of technological operations (structure and order),
  - selection of technological processes for the considered operation,
  - selection of the machine tools and tooling,

- determination of cutting conditions.
- *Stage of the after-treatment selection :*
- selection of the type of coating and the electroplating line,
- selection of surface treatments within special technical requirements (e.g. polishing).

Troubleshooting process of decision-making requires the creation of acceptable alternative solutions from the point of view of the technological capacity of the production system and production profitability in terms of the production costs minimization and the processing cycle time. Taking into account the level of description precision to describe the technological process structure, variants are created at different levels, e.g.:
- variants of technological processes,
- variants of technological operations,
- variants of technological tooling.

The number and complexity of options at each level depends frequently on the size of production of machine parts and the company's manufacturing capabilities. It should be noted that while increasing levels of creating variants there is a simultaneous increase of the level of description precision of the technological process.

Elaboration of the Method of Knowledge Representation about Structure of Machine Parts

In the knowledge management system there is a symbolic processing of information, and therefore the construction description should be expressed using symbols. Symbols in the form of alphanumeric character strings, are built on the basis of assumed semantics and a language syntax of design element description. The method of the symbolic knowledge representation is based on the identification of geometric construction features of the machine parts.

The process of creation of the knowledge symbolic representation about the structure of machine parts runs in stages. At the first stage, characteristic dimensions are determined assigning appropriate symbols to them. Characteristic dimensions are the element's overall dimensions as well as the dimensions of the element's relevant functional surface, interacting with the other elements surfaces. At the next stage of the construction, a construction division into elementary objects takes place, recording them using symbols. Elementary objects describe surface groups or an element's individual surfaces. They have been characterized by construction geometrical features. It was assumed that these traits can be permanent and variable. Permanent characteristics are closely associated with the elementary object, and their value is determined in advance and is not changed during the production preparation. While the variable features are determined during consultations with the knowledge management system.

The starting point of the elaboration of an exemplary knowledge representation about the structure of machine parts is the design documentation analysis of hydraulic actuators. Analysed hydraulic cylinders are double-acting. They consist of a cylinder tube with power supply terminals, the withdrawable piston rod, the sleeve gland which closes cylinder and a set of rings and gaskets. The end of the piston rod and the cylinder tube are equipped with brackets for mounting the cylinder.

From the distinguished group of actuators elements, an exemplary group of piston rods was selected for the presentation purposes, for which a symbolic knowledge representation has been elaborated. Fig. 1 shows the structure of the piston rod, in which features elaborated according to the adopted representation method have been marked. Characteristic dimensions of the piston rods have been determined that are assigned to the symbols, namely: the total rod length (L), the maximum transverse dimension of the rod (d1) and the diameter of the cylindrical finishing (d). The next step is the construction of the elementary objects. The elementary object has been adopted concerning cylindrical finishing of the piston rod (GC)

and a group of elementary objects linked with the hydraulic actuator's elements interacting with the piston rod, such as:

- the end of the piston rod from the side of the press - KT,
- the end of the piston rod from the side of the bracket - KU.

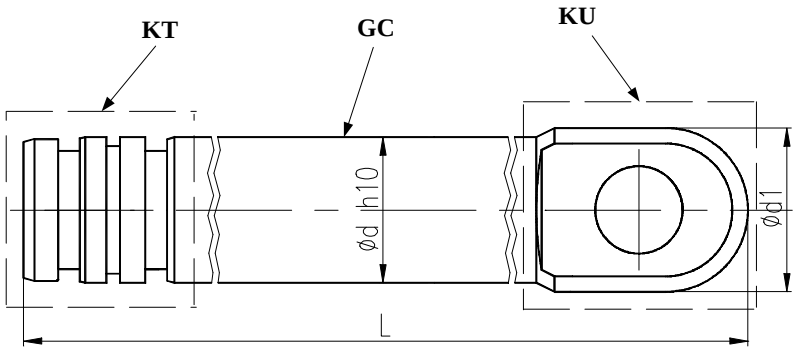

Fig 1. The structure of the hydraulic piston rod

KT group includes elementary objects, for which permanent and variable dimensions have been selected, as shown in Fig. 2 and described in Table 1.

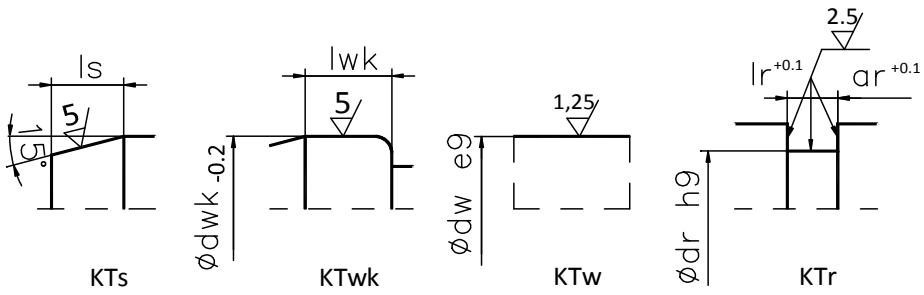

Fig 2. Geometric construction features of the elementary objects of the KT group

Table 1: Description of the construction features of the KT elementary objects and of the GC piston rods

Object symbol	Geometric construction features			
	variable		permanent	
	name	nbol	name	symbol
C	diameter cylindrical finishing	d	y class	10
			ss	,63[µm]
Ts	the length of the conical surface	ls	angle of the cone surface	f = 15°
			roughness	Rkts = 5 [µm]
KTwk	the length of the cylindrical surface	wk	roughness	Rktwk = 5 [µm]
	the diameter of the cylindrical surface	wk	value of the diameter tolerance	Tdwk= -0,2[mm]
KTw	ameter	dw	y class	ITdw = e9
			roughness	Rktw =1,25 [µm]

cont. Table 1.

Object symbol	Geometric construction features			
	variable		permanent	
	name	nbol	name	symbol
KTr	of grooves	n	value of the width tolerance	Tlr = +0,1 [mm]
	the diameter of the groove bottom	dr	accuracy class	ITdr = h9
	h of the groove	lr	roughness	Rktr = 2,5 [μm]
	distance from the cylindrical finishing	ar	value of the distance from the cylindrical finishing	Tar = +0,1 [mm]

Fig. 3 shows variants of elementary objects KU, and Table 2 describes the permanent and variable characteristics.

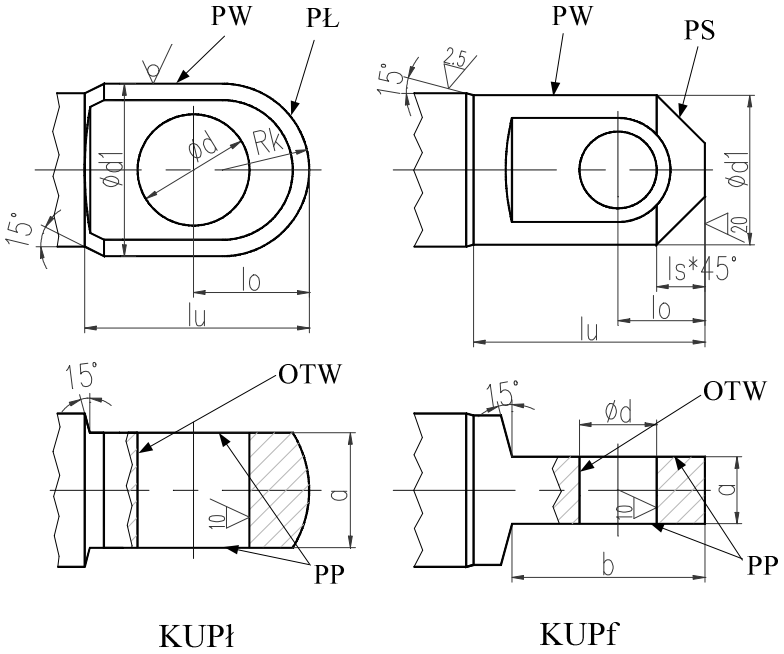

Fig 3. Geometric construction features of the KU elementary objects

Table 2: A description of the construction features of the KU elementary objects of the piston rods

Group symbol	Object symbol	Geometric construction features			
		variable		permanent	
		name	nbol	name	symbol
KUPł		tip length	lu	angle of the cone surface	f = 15°
	PW	diameter	d1	-	-
	PŁ	radius of the sphere	Rk	-	-
	PP	the thickness of the bracket	a	-	-
	OTW	the hole diameter	d	roughness	Rotw =10[μm]
		the distance of the hole axis	lo		

cont. Table 2.

Group symbol	Object symbol	Geometric construction features			
		variable		permanent	
		name	nbol	name	symbol
UPf		tip length	lu	angle of the cone surface	f = 15°
				roughness	Rf = 2,5 [μm]
	PW	diameter	d1	-	-
	PS	the length of the conical surface	ls	roughness	Rps =20[μm]
				angle of the cone surface	fs = 45°
	PP	width of the handle	a	-	-
		length of the handle	b		
	OTW	the hole diameter	d	roughness	Rotw =10[μm]
		the distance of the hole axis	lo		

A procedure of assigning values to the variable features in the knowledge management system is introduced, which results in obtaining knowledge about the structure of the selected machine part.

Method of the knowledge representation about the structure of the technological process

A symbolic knowledge representation about the technological structure in the construction of the knowledge management system should be elaborated. Such representation is constituted by appropriate symbols, which in conjunction with symbols representing the input data and the construction of the machine part allow to generate the technological process for the machine part. The basis for the construction of the representation is to analyse the construction and technological documentation of selected machine elements. This analysis is conducted in order to determine the relationship between construction and the technological process.

In the initial stage, sets of symbols based on the use of the particular variants in technological process designs have been created. Then a method of recording of the symbolic knowledge representation basing on the description of required technological operations in the process has been assumed. The construction scheme and the forming method of the technological symbol has been shown in Fig. 4.

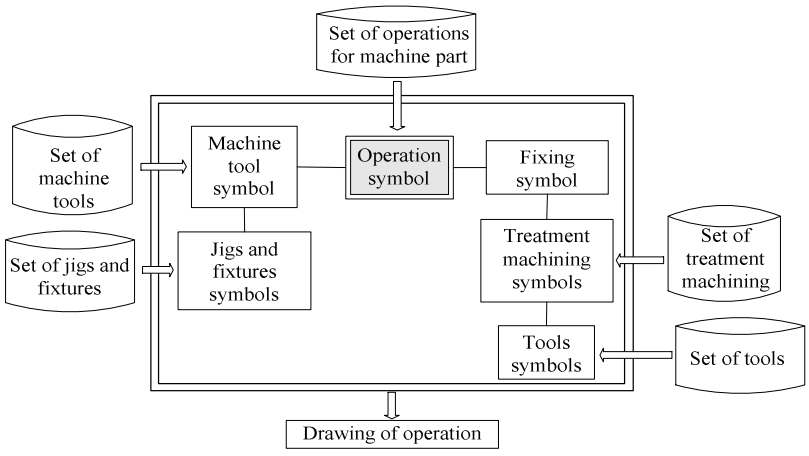

Fig 4. The structure of the technological symbol in the knowledge representation

Recording of the technological symbol is based on the following format:

{<OPERATION>, <MACHINE TOOL>, <FIXING>, <TREATMENT MACHINING>, <JIGS AND FIXTURES>, <TOOLS>}

On the basis of the symbol structure of the technological process, information is obtained which is represented in a form of a description and operations drawings, which occur in the technical documentation of the knowledge management system.

An exemplary technological symbol in a description of the selected structure of the technological process for machine parts such as sleeve, looks as follows:

{Turning, EMAG MSC-22, Z1, TCz(L1), WZ(Dwz), WK(Dw), Z2, TCz(L), TZ(Dzz), TK(Dz), (A243/52, A259/25), (hR117.26_3225-TNMG160408, hR123.26_3225-CNMG2204, MAUb-150, MMZb/1)}

This symbol represents the name of the machine tool (EMAG MSC-22) on which there is the machined sleeve in the enterprise, the symbols of used jigs and fixtures (A243 / 52 A259 / 25), as well as cutting tools and measuring equipment (e.g. hR117.26_3225-TNMG160408 , MAUb-150). Fig. 5 is also associated with this symbol, shows a method of the sleeve processing.

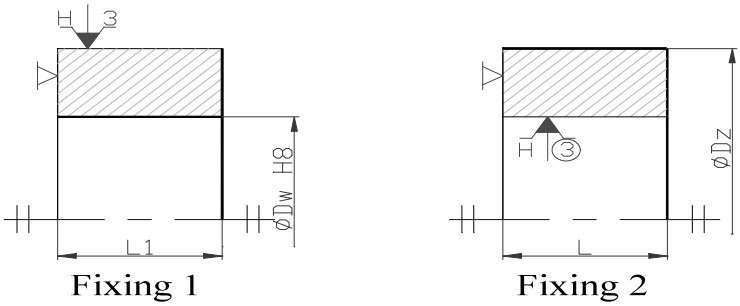

Fig 5. An exemplary schedule of the sleeve processing

The Use of the Decision-Making Rules in the Designing of Technological Processes

On the essence of the technological processes of machine parts, a close dependence derives between the construction and the structure of the technological process. This dependence is the result of the analysis of the production's technological preparation of machine parts and research on the selection of technological processes and technical resources required for their implementation. On this basis, a diagram of the design process using the symbolic knowledge representation about the construction and the technological process structure of machine parts has been elaborated, as shown in Fig. 6.

A key element of the designing process (Fig. 6) are decision rules. These rules constitute an elementary part of the knowledge base system, and on their basis, the decision problems are solved. The primary objective of the application of the rules is as follows:

- presentation of the dependences between the input information about the decision-making problems, and the knowledge that describes the solutions to these problems,
- record of relationships appearing in the description of the construction element - the rules usually show the arrangement of the description (characteristic dimensions and elementary objects) and the order of assigning values to the variable dimensions,
- the creation of knowledge characterizing the structure of the designed technological process - starting with the record of the highlighted symbol of the structure based on rules describing a symbolic representation of the process structure, it is possible to obtain information about the process according to the assumed level of precision of the description.

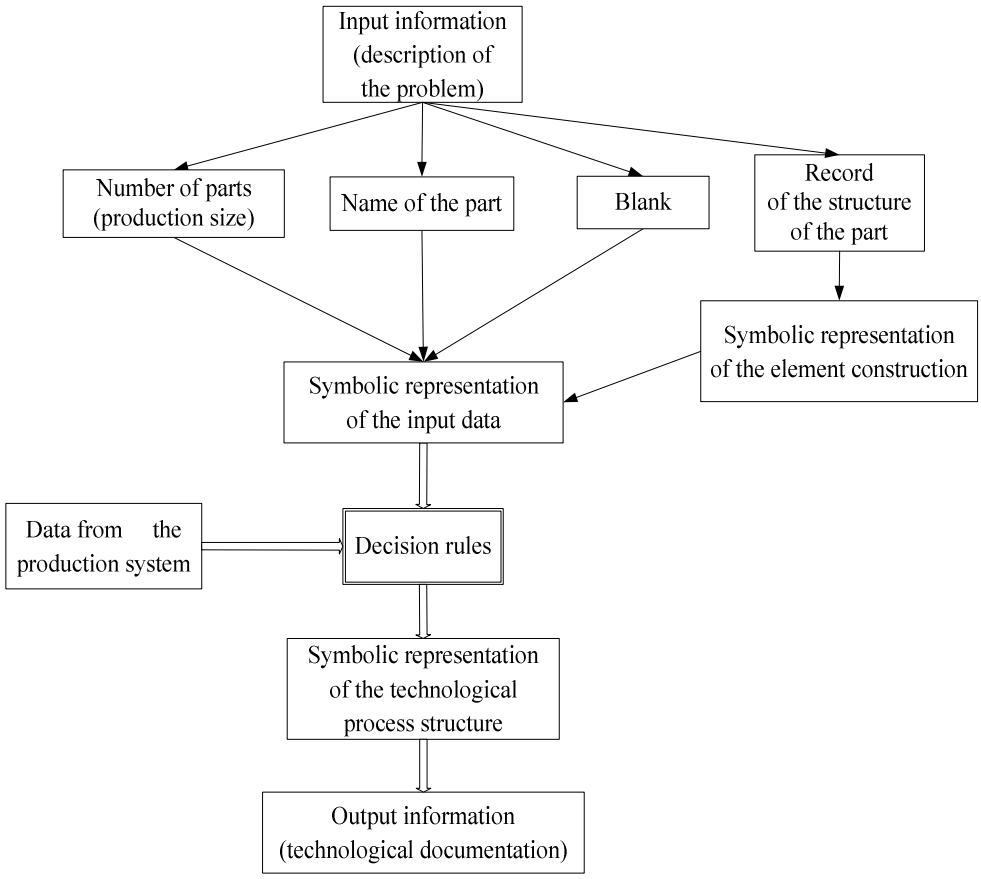

Fig 6. A scheme of the designing process using the symbolic knowledge representation

The general structure of decision rules are as follows:

If <*construction*> **then** <*structure of the technological process*>

The conditional part of the rule include a description of the distinguished components of the machine element, while the activity part includes corresponding description of the technological process structure (operations, treatment machining, etc.) according to a predetermined level of precision.

In the construction of the decision rules, the elaborated symbolic knowledge representations concerning the construction and the structure of the technological process of machine parts have been used. In the conditional and action part, corresponding symbols have been introduced, and the construction of these rules takes the following form:

If <*the symbol of the construction representation*>
then <*the symbol of the technological process structure*>

It can be generally stated that the elaboration of the decision rules constitutes the basic knowledge representation in the construction of knowledge management systems in a manufacturing company and will be used in the computer record of the technological knowledge base.

An example of the construction of decision rules will be presented for the problems of production's technological preparation in the type of piston rod of hydraulic cylinders. The research of the impact of

the elements characteristic dimensions on the selection of the blank and operations in the technological process lead to the creation of examples of decision rules for the following decision problems:

- *for the selection of the blank*

R1: **If** the maximum transverse dimension d1 is greater than or equals 40% of the diameter of the cylindrical finishing, that is d1> = 1.4d **then** the input material should be the forging matrix

R2: **If** the maximum transverse dimension d1 is smaller than 40% of the diameter of the cylindrical finishing, that is d1< 1.4d **then** *the the input material should be the rolled bar*

- *for the selection of the initial operation*

R3: **If** the input material should be the rolled bar **then** perform the operation of the material cutting **and** milling operation and centring

R4: **If** the input material should be the forging matrix **then** perform milling of faceplate and two-sided centring

Further examples of the decision rules construction related to the research of the impact of the type of piston rod's elementary objects on the type and sequence of technological processes in the prime machining. A given object, of a specific net-shape precision corresponds to a set of procedures, arising from the allocation of processing into: roughing, shaping and finishing (Table 3). For the object's variable construction features, based on the norms of technological allowances, intermediate dimension values, characterizing a particular treatment, are assigned.

Table 3: Examples of the dependences between the type of the elementary object and technological treatments

Object symbols	Description of the technological treatments	Technological treatment symbols
GC	Rough turning to the diameter d on the length Ldz Turning to the diameter dk on the length Ldk Burnishing to the diameter d h10 on the length Lgc	TZGC(dz, Ldz) TKGC(dk, Ldk) DGC(d, Lgc)
KTs	Turning the conic area 15□ □on the length ls	TKKTs(ls)
KTwk	Turning to the diameter dwk on the length lwkk	TKKTwk(dwk, lwkk)
KTw	Turning to the diameter dw on the length lw	TKKTw(dw, lw)
KTr	Turning a groove lr to the diameter dr in the distance ar	TKKTr(lr, dr, ar)
PW	Rough turning to the diameter d1z on the length lu Turning to the diameter d1 on the length lu	TZPW(d1z, lu) TKPW(d1, lu)
PŁ	Rough turning a sphere of the radius Rk Turning a sphere of the radius Rk	TZPŁ(Rk) TKPŁ(Rk)
PS	Rough turning the conic area on the length ls Turning the conic area on the length ls	TZPS(ls) TKPS(ls)
PP	Milling the first side of the bracket to the width a1 on the length b Milling the second side of the bracket to the width a on the length b	F1PP(a1, b) F2PP(a, b)
OTW	Rough drilling a hole d0 in the distance lo Drilling a hole d in the distance lo	Ww(do, lo) Pw(d, lo)

Basing on Table 3 one can generate the following examples of decision rules:

R1: **If** GC(d) **then** TZGC(dz, Ld) **and** TKGC(dk, Ld) **and** DGC(d, Lgc)

R2: **If** KTs(ls) **then** TKKTs(ls)

R3: **If** KTwk(dwk, lwk) **then** TKKTwk(dwk, lwkk)

Introduced symbols of knowledge representation in the conditional and action part of the decision rules are described by information collected in the knowledge management system. Thanks to this, the system supports technological preparation of production by generating proposals for solutions to the decision-making problems in the process designing.

The Construction of a Framework Representation of the Technological Knowledge

Decision-making problems in the area of technological processes may be very complex and therefore it is often required to elaborate a numerous set of rules in the knowledge management system. It is therefore deliberate to appropriately group rules according to the existent stages of designing. It is required that all rules are recorded in the knowledge system base, which in this case has a modular design. From various methods of knowledge representation, the framework representation has been chosen as the most appropriate method of meeting the requirements of the knowledge base recording.

The base of the presented representation are the frames. Frames allow to organize the knowledge base in such a way that the rules which are representative of the knowledge in the area are clearly separated from the rules necessary for the proper operation of the system. The frame is a structure describing the considered object and allows declarative and procedural knowledge representation. It consists of a so called substructures - slots, depicting some properties or characteristics of the object. Slots are divided into even smaller knowledge pieces, which are called facets. All frame components have unique names, making them easy to identify and record in the knowledge base. A characteristic feature of the knowledge framework representation is the ability to divide the acquired knowledge into information sets, responding to the stages and decision-making problems in the process design. The advantage of this representation is the possibility to group information concerning selected portion of knowledge in the form of a frame, which facilitates verification and modification of the system's knowledge base.

The scheme of construction of a framework knowledge representation has been shown in Fig. 7. The presented knowledge representation has a procedural and declarative character. The declarative nature of the representation results from the elaborated sets of rules, in which the information needed to solve the decision-making problems has been declared. On the other hand, the procedural representation is based on the frame structure, in which the rules are recorded according to the established procedure of the order of their use. Elaborated frames can be combined and a hierarchical structure of the framework is formed. In such a structure, it is possible to inherit knowledge from the parent frame to the sub frame by means of respective sub-facets. Parent frame has a fixed set of facets, whereas in sub frames besides facets, which are permanently placed in the structure, there are still facets transferred from the parent frame.

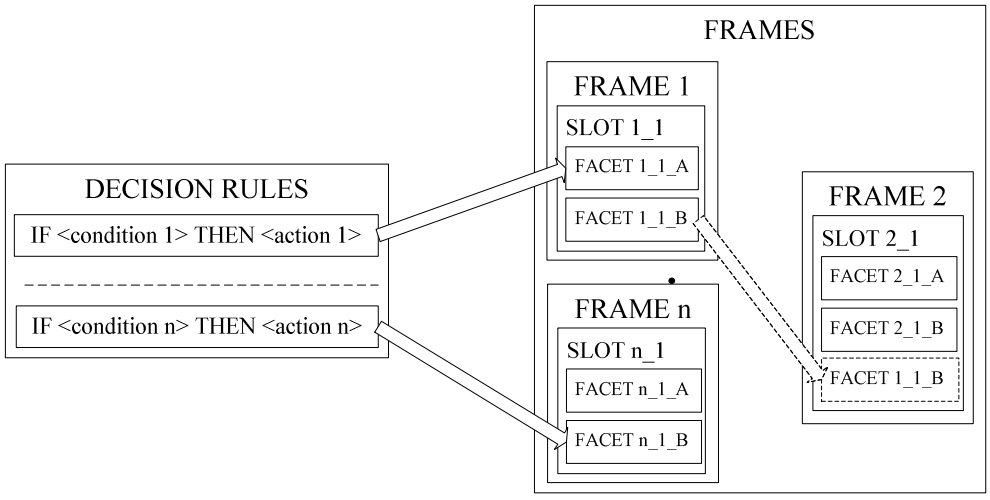

Fig 7. The scheme of construction of a framework knowledge representation

An example of a framework knowledge representation concerns the selection of the type of primary operations in the technological preparation of production of selected machine elements. An elaborated frames with decision rules has been shown in Fig. 8.

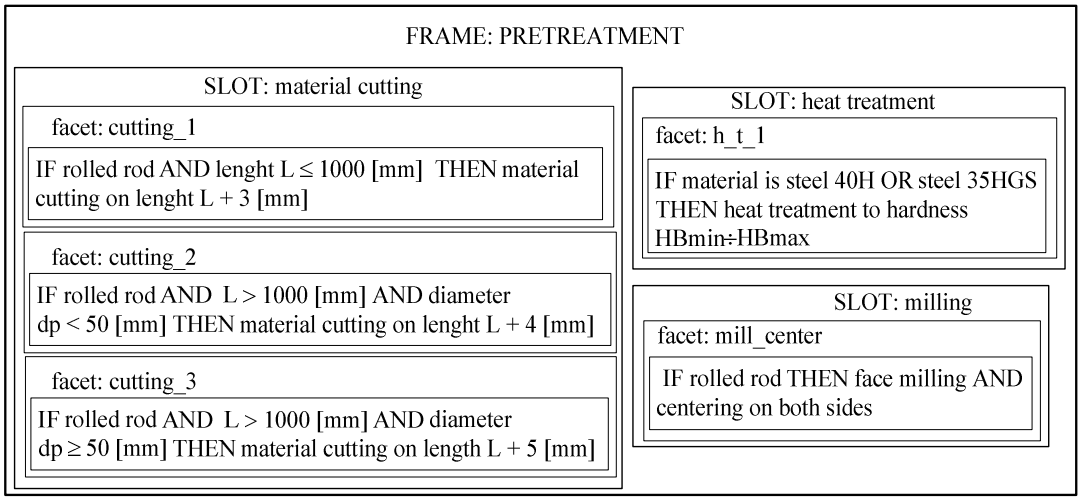

Fig 8. An example of a frame for the primary operations selection

The presented frame contains slots, which correspond to the following preliminary operations: the material cutting, heat treatment and milling. The particular slots contain facets, in which decision rules for the selection of the appropriate operation have been introduced. These rules have been filled with input and output information for making decisions in the technological processes designing.

Conclusion

Elaborated methods of knowledge representation have been aimed at the construction of knowledge management systems. It is associated with the processes of knowledge elaboration, from the knowledge acquisition for the sake of the system through the construction of the knowledge representation and recording of the knowledge base system. Presented knowledge structure is introduced to the knowledge management system in the enterprise. This requires the use of an appropriate software tool.

The research related to the elaboration of the construction of the symbolic technological knowledge representation have been based on expert methods. To substantiate the choice of such methods is the nature of the knowledge itself, which is embedded in the realities of the company and includes a set of information about products, processes and production systems. The elaborated method of knowledge representation supports key processes of knowledge management in the production company, hence it is necessary to use in this case, the knowledge of specialists-experts in the preparation and execution of production processes. This allows mapping of the experts' reasoning, who solve particular decision problems, which require detailed knowledge resources. Elaborated methods facilitate decision making related to the technological preparation of the machine parts production.

Taking into account the specifics of the knowledge management system one may link the effects of their work with the following basic benefits for the company:

- honing of processes and products,
- improvement of the information flow in the process.

By establishing a common knowledge base it is also possible to integrate it with the enterprise's management system. It is a condition for the proper functioning of computer systems in manufacturing companies.

Abstract

Organizations have adopted information communications technologies (ICT) at various time lines driven by business needs or due to technologies evolution. This has given raise to disparate systems based on various technologies and spaghetti architecture.

This paper discusses why it's critical for organization to adopt the emerging technologies. The reasons behind the current state of the architecture. Suggests how organizations can make use of, The open group architecture framework (TOGAF) to develop enterprise architecture.

Then they paper emphasis on the importance of Capability Maturity Assessment. The current practice of Capability Maturity Assessment by TOGAF, its drawbacks. Then based on the practical experiences, proposes Comprehensive Capability Maturity Model Assessment (CCMM) that covers across the phases of Architecture development method that provides the assessment of maturity to be more realistic.

Keywords: Emerging Technologies, Enterprise Architecture, TOGAF, The Open Group Architecture Framework, Capability Maturity Model. CMM, Architecture Development Method, ADM

Introduction

It's critical for Enterprises to embrace the emerging technologies such as cloud, big data, social media, Internet of Things, analytics etc. for the following purposes:

- to improve the quality of service or products
- to reduce the cost of the services or products
- to reduce the operational cost of technologies services
- to innovate and enhance the services or products offered

Taking by examples the organizations such as Motorola, Nokia, Kodak (Lucas & Goh 2009), It has been proven that organizations have lost their market leadership or perished if they do not adopt technologies for betterment of services or products offered. Thereby it's critical for organizations to adopt technologies for their survival.

Purpose

The purpose of this paper is to propose a Comprehensive Capability Maturity Model (CCMM) that will guide adoption of emerging technologies to meet the organization strategy. The CCMM also helps to

enable the business objectives in a cost effective and manage future proofing of technologies stack as far as possible.

Background

Enterprises have adopted information communications technologies (ICT) at various time lines driven by business needs or due to technologies evolution. ICT have evolved from standalone main frames to multi-tier systems to current virtualized environment where the infrastructure stack is a software code (Nelson-Smith 2013) rather than a physical hardware. To manage the information communications technologies effectively and efficiently various frameworks and methodologies have evolved.

The new buzz word 'digital transformation' refers to the changes associated with the application of digital technologies in all aspects of human society achieved through adoption of emerging technologies. With the hyper connected world, it's critical for the enterprises survival to take the path of digital transformation through adoption of emerging technologies.

Technologies evolution has made it affordable by large and small enterprises and common man, hyper connected world that enables social media as part of day to day life enabling its acceptance for personnel and commercial usage. Big data and analytics enable to get new insights of human behavior. Organizations need to reinvent itself in the Digital Age to be competitive or to exist.

Emerging technologies are going through a massive transformation causing technological shifts:

- Mobile networks becoming faster.
- Mobile phones computing capacity similar to computers
- Cloud computing with its unlimited computing power that is affordable by small organizations.
- Infrastructure or Platform or Software-as-a-service compliant with the standard industry certification has created credibility on the security stack. Due to this organizations are replacing on-premises hardware and software with service stack. Social media acceptance by private organization for business and work
- Bring your own device being a norm in organizations
- Employees being more tech savvy and acceptance of technologies for conducting day to day task in office.

Emerging technologies adoption brings in its own challenges such as technical skills, managing risk in embracing new technologies, resistance from the business to learn new way of using the systems, organization culture & risk appetite of organizations and vendor support available, in summary it's art and science to embrace cutting edge technologies. With the emerging technologies that is disruptive in nature organizations need to change the traditional business model across the organization to be successful.

Moving forward to embrace emerging technologies it's critical for the enterprise to assess the current state of the technologies stack, identify the desired future technologies stack (Group 2011). We can give an analogy as doctor assessing the health of the patient before the treatment can be prescribed. Depending on the ailment of the patient the doctor may prescribe ad hoc check or complete end to end health check of the patient

Problem

Digital Technologies that is pervasive and affordable is been used by humans to manage the day to day chores. Humans are becoming dependent on the technologies for day to day chores. Mobile, Social media and globalization has created transparency where humans are able to compare the cost of

products or services offered by private or government organization. This has given rise to adopt technologies more efficiently by government or private agencies to improve the quality of service or product.

In the last few decades enterprises have invested millions and billions of dollars on the Technologies. For many organizations, though technologies adoption was inevitable, it has not given the desired benefit. The technologies stack of typical enterprises adopted in the last few years are all based on proprietary (Gunasekaran & Ngai 2004) and hard coded. This has given rise to high operational cost, lock in with the vendor and limiting the innovation that can be achieved with adoption of technologies

In the recent years technologies evolution has given rise to new business model that is utility model pay per usage. This resulted in technologies being seen as commodity, meaning the enterprise can buy both hardware and software technologies on the need basis rather than upfront investment to buy and own the hardware and software. This changed business model of upfront investment the Capital expenditure to Operation expenditure that pay per usage is disrupting the business model. The above factors influences the enterprise to change the existing technologies to adopt the cutting edge technologies with minimal budget and reduced risk.

Impact on the organizations due to ever evolving technologies changes:

- How to identify the technologies that is right and relevant to an organization?
- How to future proof technologies? (A million dollar question)
- How to choose the technologies stack that meets the objectives of the business needs?

In this paper we first discuss the emerging technologies, the current technologies stack of typical enterprise, next the factors that contributed to the current technologies stack. Further the paper briefly describes the concepts of enterprise architecture, capability maturity model, the current practices utilized for capability maturity assessment, the proposed approach goes beyond the current practice of maturity assessment, comparison of the current maturity model assessment with proposed maturity model assessment, further research work that needs to do based on the new approach of Comprehensive Maturity Model Assessment (CCMM) and finally the conclusion.

Research Methodology

The research is based on literature review and experience gained through involvement in enterprise architecture projects done in Australia, Brunei, Mongolia, Philippines and Vietnam

Emerging Technologies

Organizations always prefer to embrace cutting edge technologies either that are matured or evolving. This cutting edge technologies also known as Emerging technologies lack key foundational elements, namely a consensus on what classifies a technologies as ‘emergent’. The five key attributes of emerging technologies are: radical novelty, relatively fast growth, coherence, prominent impact, and uncertainty and ambiguity (Rotolo, Hicks & Martin 2015).

Technologies that exist, that will evolve in next five to ten years capable of disrupting the existing model and changes the way we communicate in the social fabric of society also known as emerging technologies. This may include cloud computing environment, social media, big data, analytics, Internet of Things and many more.

Emerging technologies affects:

- Lead to the rapid development of new capabilities;
- Are projected to have significant systemic and long-lasting economic, social and political impacts;
- Create new opportunities for and challenges to addressing global issues;
- Have the potential to disrupt or create entire industries

Open Platform 3.0

The Open Platform 3.0(Group 2016) (Group 2016) (Group 2016) (Open Platform 3.0 2016) focuses on new and emerging technologies trends converging with each other and leading to new business models and system designs. The emerging technologies can be broadly classified as the following categories:

- Mobility
- Social networks and social enterprise
- Big data analytics
- Cloud computing
- The Internet of Things (networked sensors and controls)
- Other technologies may be taken on board as the Platform develops.

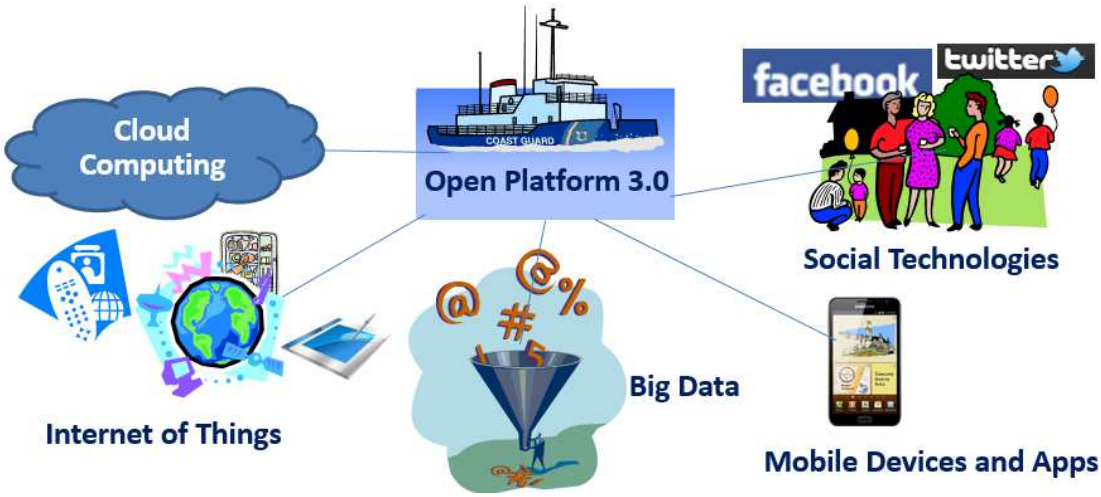

Fig 1. Open Platform 3.0

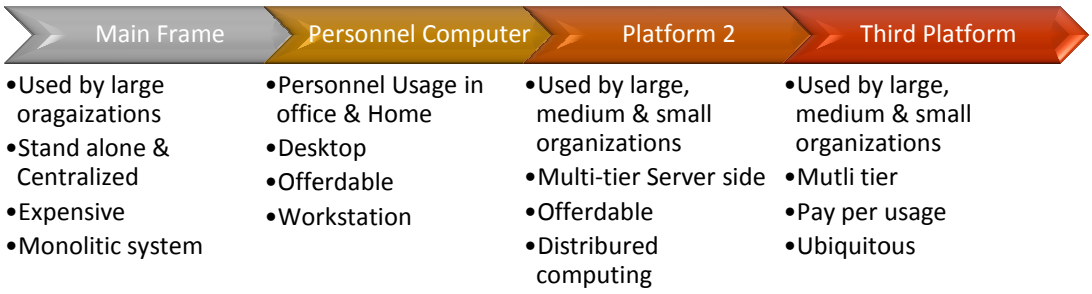
Open Platform 3.0 advances The Open Group vision of Boundary less Information Flow achieved through global interoperability in a secure, reliable, and timely manner(Group 2016); there by helping enterprises to use these technologies and reap their business benefits. The Open Platform 3.0 describes the business and technical environment and identifies the fundamental requirements for the platform.

Technologies has evolved from main frame stand alone, personal computers used for day to day, distributed layer to current open platform 3.0 (Museum 1996),



Gartner Emerging Technologies Hype Cycle

Gartner's (Walker 2015) (Walker 2015) releases Emerging Technologies Hype Cycle that brings together the most significant technologies. This provides insight into emerging technologies trends that may disrupt an organization business model. This Hype Cycle provides Market Excitement, Maturity and Benefit of Technologies, so organizations needs to monitor this cycle

Current technologies stack of typical enterprise

Technologies usage in organizations has started since early 1950's from the main frame to current open platform 3.0. Organizations that are large and Government agencies have adopted technologies from last few decades. They have adopted technologies as they evolved and to meet the business needs. This resulted in spaghetti of disparate system connected that is based on various technologies, some technologies are proprietary and some are open standard. The resulting architecture is as below

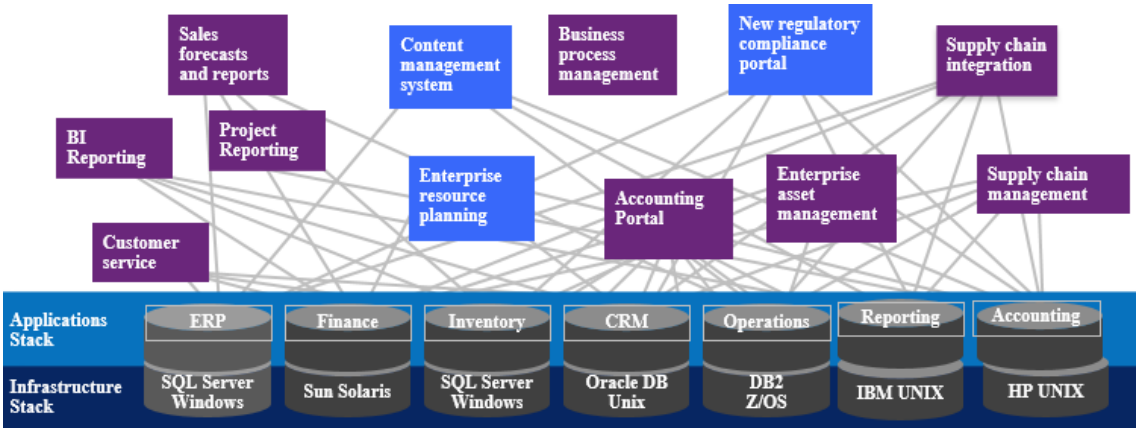


Fig 2 Spaghetti Architecture due to technology adoption at various timeline

The current architecture of typical organization

Architecture is man-made building or structure; a carefully designed object such as a chair, a spoon; a design for a city, town, park, or landscape; a well-designed website, student management system, e-commerce website such as ebay.

The architect models the stakeholders' vision (an individual or organization that has with an interest in the enterprise) and creates an architecture definition that will be the basis of developing an information system (Osvalds 2001).

All the information systems either stand alone or grouped together has followed an Architecture. As technologies has evolved at various time line and the systems are commissioned based on technologies

evolution has resulted in an architecture that is rigid. We can relate to massive urbanization, accompanied by the rapid expansion of cities and metropolitan regions that resulted in explosive growth giving raise to unplanned cities (Angel et al. 2012).

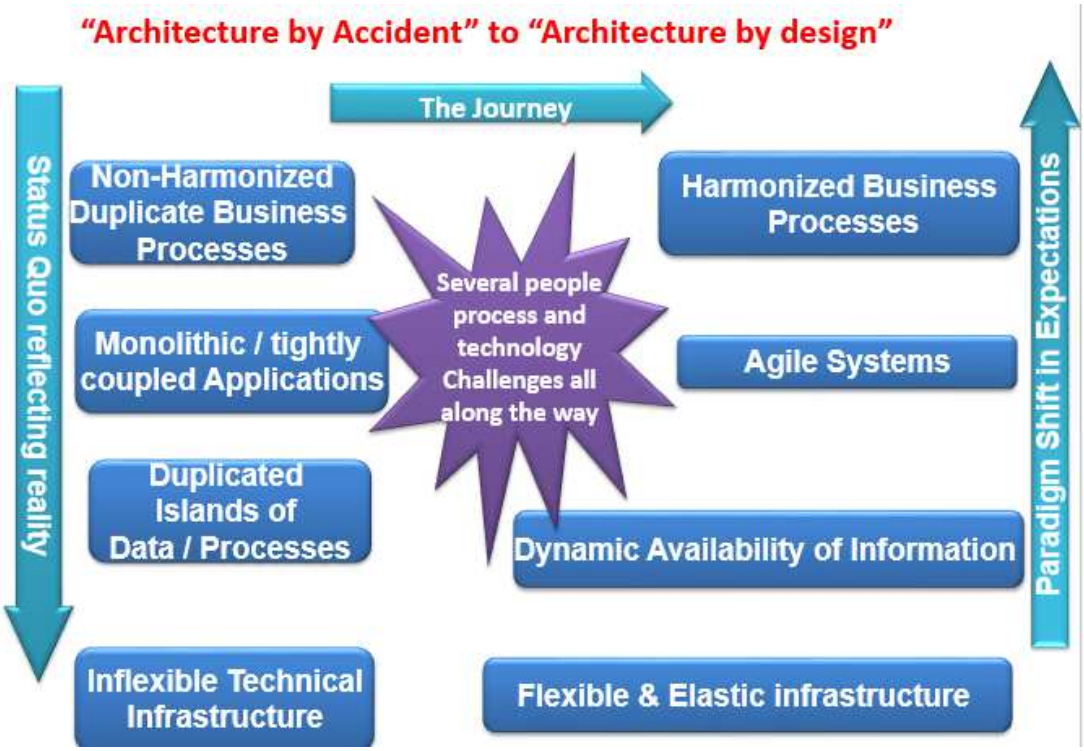

Fig 3. AS IS Current Architecture to TO BE Dynamic Architecture

Enterprise architecture

Enterprise as per The Open Group (Group 2011) is a collection of organizations that has a common set of goals. For example, a government agency, a whole corporation, a division of a corporation, a single department, or a chain of geographically distant organizations linked together by common ownership.

Enterprise in the context of ''enterprise architecture'' denote an organization information and technologies services, processes, and infrastructure and the architecture that cut across the multiple systems, functional groups within the enterprise.

According to Gartner (Gartner 2008) Enterprise architecture is the process of translating business vision and strategy into effective enterprise change by creating, communicating and improving the key requirements, principles and models that describe the enterprise's future state and enable its evolution.

The scope of the enterprise architecture includes the people, processes, information and technologies of the enterprise, and their relationships to one another and to the external environment. Enterprise architects compose holistic solutions that address the business challenges of the enterprise and support the governance needed to implement them.

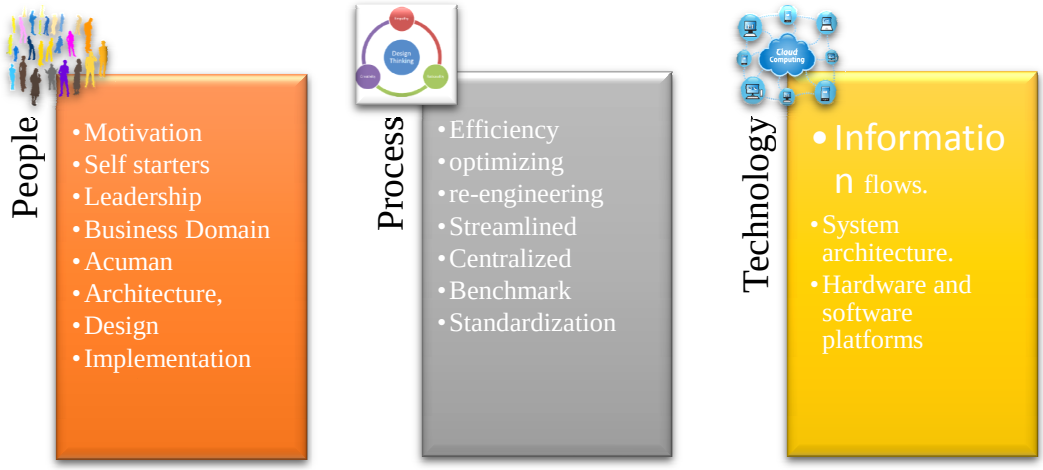

Fig 4. People, Process and Technology

According oxford dictionary an framework is a basic structure underlying a system, concept, or text: To implement enterprise architecture we need an framework based on open standards well accepted in the industry as they are seventy seven enterprise architecture frameworks (Takahiro Yamada 2016).

Benefits of Enterprise Architecture

Organizations tremendously benefit with incorporation of enterprise architecture practice

- A more efficient business operation:
  - Lower business operation costs
  - More agile organization
  - Business capabilities shared across the organization
  - Lower change management costs
  - More flexible workforce
  - Improved business productivity
- A more efficient IT operation:
  - Lower software development, support, and maintenance costs
  - Increased portability of applications
  - Improved interoperability and easier system and network management
  - Improved ability to address critical enterprise-wide issues like security
  - Easier upgrade and exchange of system components
- without sacrificing architectural coherence

- The ability to procure heterogeneous, multi-vendor open systems
- The ability to secure more economic capabilities(Group 2011)

What is The Open Group Architecture Framework (TOGAF)

TOGAF is an architecture framework - The Open Group Architecture Framework. TOGAF provides the methods and tools for assisting in the acceptance, production, use, and maintenance of an enterprise architecture. It is based on an iterative process model supported by best practices and a re-usable set of existing architecture assets. TOGAF embraces ISO/IEC 42010:2007 terminology though not completely (Group 2011).

Irrespective of any domain there are four layers called as core architecture and two layers cross cutting across the core layers accepted in overall enterprise architecture that TOGAF supports:

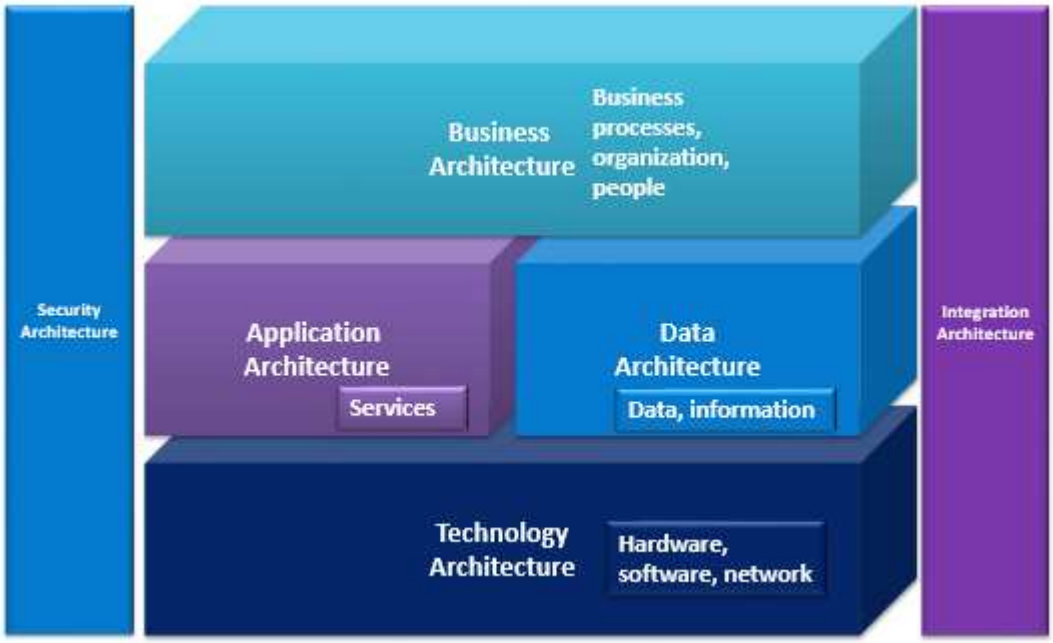

Fig 5. Core Architecture Stack

- The Business Architecture defines the business strategy, governance, organization, and key business processes and functions.
- The Data Architecture describes the structure of an organization's logical and physical data assets and data management resources. It identifies for structured, unstructured and hybrid data.
- The Application Architecture provides a blueprint of application systems to be deployed, their interactions, and their relationships to the core business processes of the organization.
- The Technology Architecture describes the logical software and hardware capabilities that are required to support the deployment of business, data, and application services.

The two cross cutting architecture layer cutting across the core layers are:

- Security Architecture: Security concerns are pervasive throughout the architecture domains and in all phases of the architecture development. Security Architecture is a set of design artefacts that are relevant for describing an object such that it can be produced to requirements as well as maintained over the period of its useful life. The design artefact describe the structure of components, their inter-relationships, and the principles and guidelines governing their design and evolution over time (Architecture 2016).

- Integration Architecture: Integration of core architectures, in business architecture its function / process; in information architecture its disparate applications / data and in technology architecture its diverse technology stack

Architecture Development Method (ADM) Phases:

The ADM describes a method for developing and managing the lifecycle of an enterprise architecture, and it's the core of TOGAF. When an organization sets up EA practice first cycle is run to identify two to five year roadmap. Subsequently its run for every key initiatives that arises based on business needs or compliances requirements, organization merger or acquisitions. ADM is iterative and incremental process across the life cycle of Enterprise Architecture.

Architecture Development Method with identified frameworks

COBIT: Control Objectives fo Information and Related Technology	Governance: Corporate, Projec Architecture and Risk	
SABSA: Sherwood Applied Busines Security Architecture	Security and Risk	

Architecture without Enterprise Architecture Framework

Organizations without enterprise architecture focus have procured the information systems based on the business needs (Gunasekaran & Ngai 2004). As information technologies in last decade was still evolving, proprietary based and organizations being risk avert, they were procuring systems that offered product support. This has caused systems to be hard coded and stuck with a vendor, costing huge maintenance cost and also high cost for system enhancement to meet the changing business needs.

Architecture with Enterprise Architecture Framework practice

Organizations with enterprise architecture practice in place, will develop the architecture building blocks based on the business requirements. Then they will choose the information systems that meets the architecture building blocks. Due to this there is no vendor lock in and also less expensive on maintenance and enhancement of information systems to meet the business needs

Capability maturity model

What Is a Capability Maturity Model (CMM)?

CMM broadly refers to a process improvement approach that is based on a process model. A process model is a structured collection of practices that describe the characteristics of effective processes; the practices included are those proven by experience to be effective.

CMM can be used to assess an organization against a scale of process maturity levels. Each level ranks the organization according to its standardization of processes in the subject area being assessed. The subject areas can be as diverse as

- Enterprise Architecture Maturity Assessment
- The Strategic Management Maturity Model
- Business Transformation Readiness Assessment
- Business Process Maturity Model (BPMM)
- Business process capability maturity model
- Data Maturity model
- The Data Warehouse Capability Maturity Model
- Information technology (IT) services
- P3M3® Portfolio, Programme and Project Management Maturity Model
- Project management,
- Organizational Change Management Maturity
- Risk management,
- Software engineering,
- Systems engineering
- System acquisition,
- Personnel management.

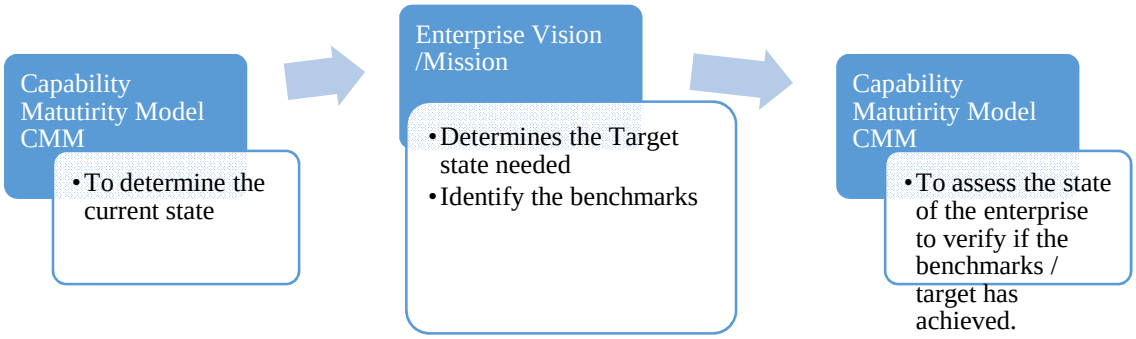

Fig 7. Capability Maturity Model overview

Maturity model provides

- a place to start
- the benefit of a community's experience and knowledge
- a common language and a shared vision
- a way to define what improvement and "maturity" mean for an organization
- a framework for prioritizing actions
- a way to define what improvement means for the Enterprise

Capability Maturity Models (CMMs) address this problem by providing an effective and proven method for an organization to gradually gain control over and improve its change processes.

IT strategy and roadmap development is most complex exercise for enterprise leaders due to the nature of diversified IT systems and architectures to address the adoption of emerging technologies. Therefore, it is important to assess the organization maturity before starting any major business transformation / periodically to identify the current maturity level which will help to define IT strategy to be realistic.

The current practices utilized for Enterprise Architecture Maturity assessment

The current Capability Maturity Model is based on US Department of Commerce (DoC) IT Architecture Capability Maturity Model (ACMM). This maturity model was developed in 2001 and lasted updated on December 2007(Commerce 2007). Information technologies as changed leaps and bounds, the maturity model has not been updated to keep in tune with the current requirement. The DoC ACMM has three sections, six levels and nine architecture characteristics.

The ACMM comprises three sections:

1. The IT architecture maturity model
2. IT architecture characteristics of operating units' processes at different maturity levels
3. The IT architecture capability maturity model scorecard

The six levels are:

- 0 : None
- 1 : Initial
- 2 : Under development
- 3 : Defined
- 4 : Managed
- 5 : Measured

The nine IT architecture characteristics are:

- IT architecture process
- IT architecture development
- Business linkage
- Senior management involvement
- Operating unit participation
- Architecture communication
- IT security
- Architecture governance
- IT investment and acquisition strategy

Why is Capability Maturity Model Assessment needed?

Before giving a treatment to a patient doctor diagnoses the patient health condition to assess the current health condition. Based on the results the treatment is prescribed to the patient.

Similarly the purpose of the assessment in an organization is to estimate the level of maturity of the enterprise IT architecture and tentatively identify various improvement areas.

We can relate to humans, those who take precautions pro-actively based on the age and condition, the other who are reactive take treatment based on the ailment. Irrespective it's necessary to do the health check on the entire system to suggest a proper treatment

Similarly it's necessary to do the maturity assessment in a holistic approach that covers the entire organization. Said that it's essential to identify the existing methods, methodologies, framework that are utilized. This gives an understanding of the current working style. Based on the target maturity model determined it's possible to recommend the appropriate framework or method or methodologies that are suitable for the enterprise.

The maturity model needed for an enterprise is based on the domain, industry vertical, type of enterprise public or private, Country, Culture, the Technologies used etc..

So each Capability Maturity Model is specially identified and tailored based on the above criteria

Capability Maturity Assessment Process

1. Define what to measure.
2. Define what can be measured.
3. Gather the data.
    a. Determine the department
    b. Group the Stakeholder

c. One to one interview

d. Organization audit reports

e. Anonymous online survey

4. Process the data.
5. Analyze the data.
6. Presenting and using the information.
7. Implementing corrective action.

Fig 8. Maturity Assessment Process

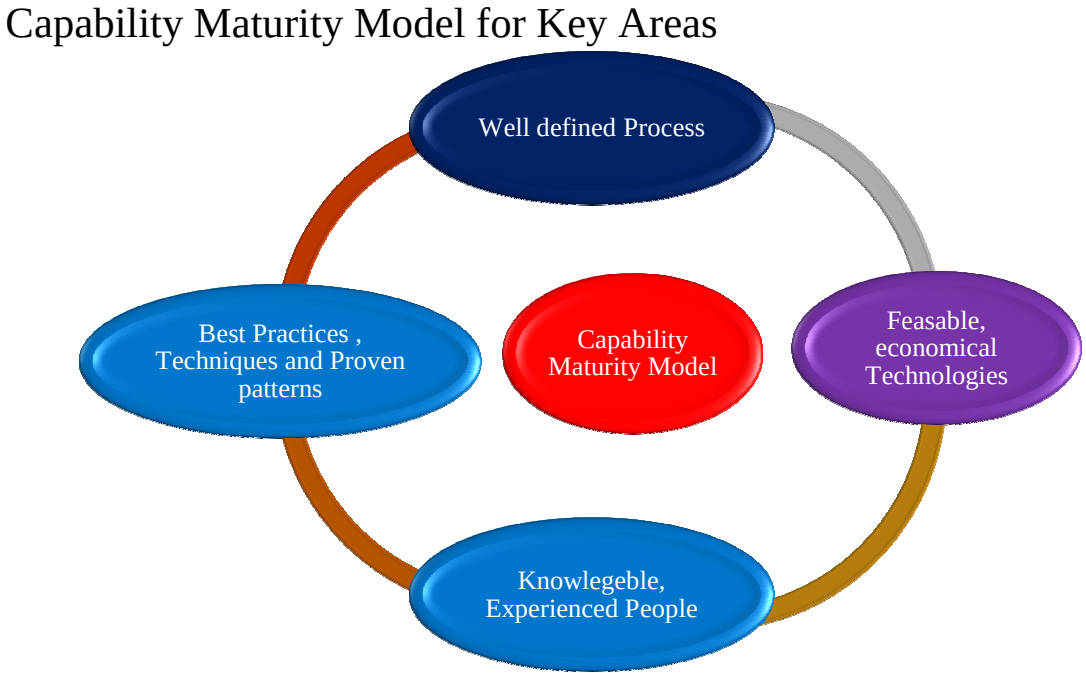

Fig 9. Capability Maturity Model Key Areas

Types of Capability maturity model

Maturity assessment has been developed at various time line based on technologies evolution. As organization relied more on technologies it was critical to assess the maturity of the organization to improve the capability of peopled, process and technologies.

From the inception of maturity model by the US Department of Defense Software Engineering Institute (SEI) began in 1986 as now they are more than fifty four maturity models (Wikipedia 2016). It's not possible to go through all the maturity model due to constraints as time, budget and resources, also it's not necessary.

Proposed Maturity Models identified based on TOGAF ADM phases

Organizations are implementing TOGAF framework for their enterprise architecture practice. Based on that we identified the key maturity models that are relevant for the phase of TOGAF Architecture development.

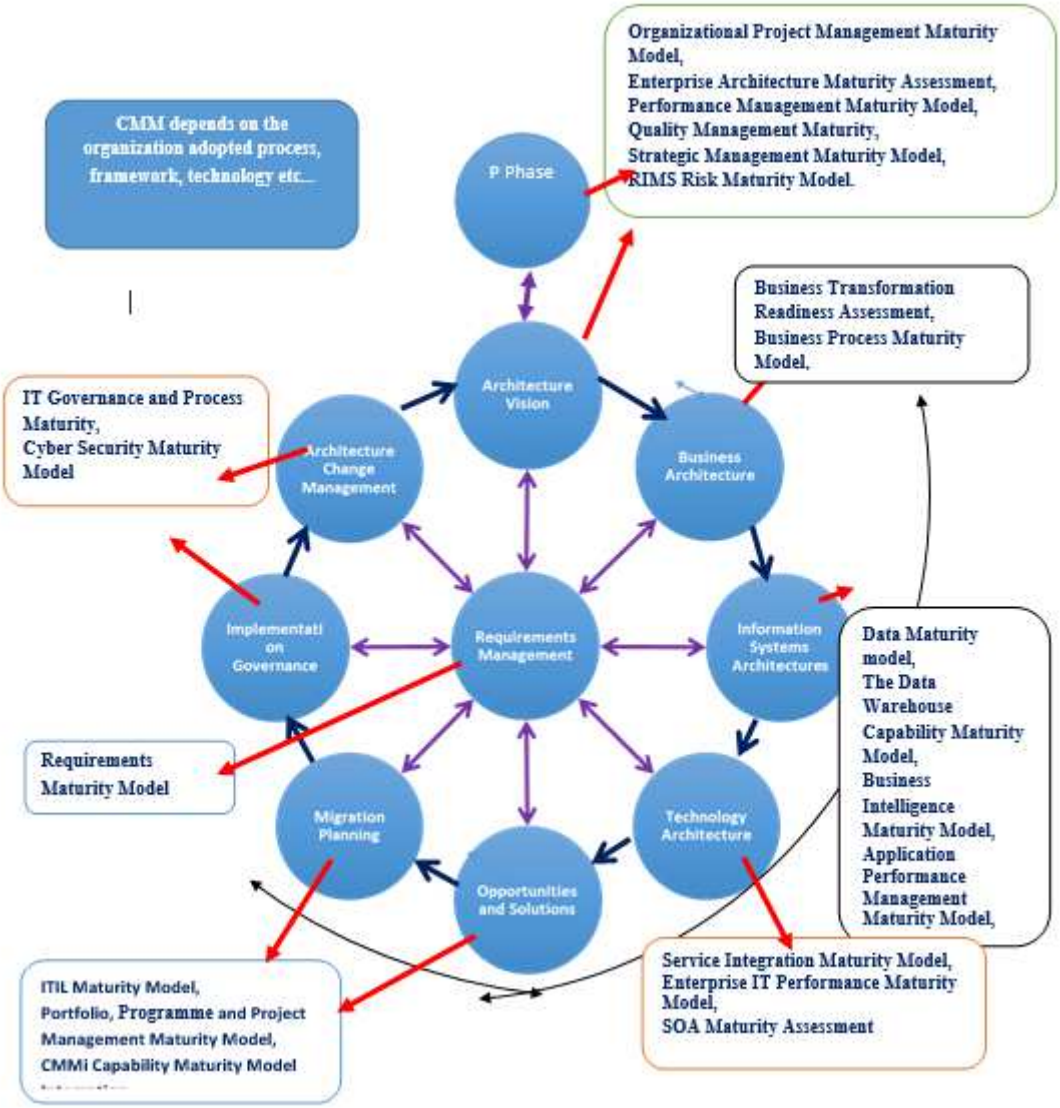

Fig 1. Suggested Maturity Models for the typical organization

Table 2 Maturity Models with purpose

ADM Phase	Maturity Model	Purpose
P:Preliminar Phase	Organizational Project Management Maturity Model,	Project Management
	Enterprise Architecture Maturity Assessment,	Enterprise Architecture
	Performance Management Maturity Model,	Performance
	Quality Management Maturity,	Quality
Phase A Architecture Visior	Strategic Management Maturity Model,	Strategy
	RIMS Risk Maturity Model	Risk
Phase B: Busines Architecture	Business Transformation Readiness Assessment,	Business Readiness
	Business Process Maturity Model,	Business process
	Business function capability maturity model,	Business function
Phase C Information Systems Architectures	Data Maturity model,	Data Model
	The Data Warehouse Capability Maturity Model,	Data ware house
Data & Applicatior	Business Intelligence Maturity Model	Business Intelligence
	Data Maturity model,	Data maturity
	Application Performance Management Maturity Model	Application Performanc
Phase D Technology Architecture	Service Integration Maturity Model,	Service Integration
	Enterprise IT Performance Maturity Model,	Information syster performance
	SOA Maturity Assessment	Service Orientatio Architecture
Phase E Opportunities & Solutions	ITIL Maturity Model,	Information Infrastructure
	Portfolio, Programme and Project Management Maturit Model,	Portfolio, Programme Project Management
Phase F: Migratio Planning	Capability Maturity Model Integration CMMI	Capability Maturit Model Integratio software development
Phase G Implementation Governance	IT Governance and Process Maturity,	Governance
Phase H	Cyber Security Maturity Model	Security

Architecture Change Management		
ADM Architectur Requirements Management	Requirements Maturity Model	Requirements

Comparison of the current maturity assessment with proposed

The current maturity model is based on outdated maturity model of US Department of Commerce (DoC) IT Architecture Capability Maturity Model (ACMM). The proposed Comprehensive Capability Maturity Model (CCMM) covers the Architecture Development Method (ADM) phases, as such the assessment is more realistic

Further research work carried on the proposed maturity model assessment

We have identified the maturity model specific to phases of the Architecture Development Method. We have utilized this technique based on our experiences learned from various enterprise architecture projects implemented. But we want to try with wider audience across the globe. As TOGAF is open standard and widely used across the world.

We will be conducting survey with enterprise architect practitioners across the world. We also conduct face to face interviews with the enterprise architect practitioners. Then we correlate the result to identify the key maturity models that are relevant based on TOGAF. Also the result produced might be applicable for certain period of time only as the maturity models changes based on the evolution of technologies

Conclusion

Organizations are utilizing The Open Group Architecture Framework (TOGAF) based on open standards to develop enterprise architecture, to help in their transformation to adopt emerging technologies.

The maturity assessment suggested by TOGAF is outdated US Department of Commerce (DoC) IT Architecture Capability Maturity Model (ACMM).

Based on project experience we have identified Comprehensive Capability Maturity Model (CCMM) assessment across the phases of Architecture development method that provides the assessment of maturity more realistic.

This maturity assessment will helps the organization to choose the right technologies stack that serves the business needs in alignment with organization strategy.

An Algorithm for Assessment and Forecasting of Industrial Enterprise Economic Stability with Probabilistic and Statistical Methods

Shmidt Andrey Vladimirovich, South Ural State University (national research university), Chelyabinsk, Russia, shmidtav@susu.ru
Khudyakova Tatyana Albertovna, South Ural State University (national research university), Chelyabinsk, Russia, khudiakovata@susu.ru

Abstract:

The article examines main contemporary approaches to assessment and forecasting of industrial enterprise stability. It explores the main issues to which attention should be paid in the formation of methodological approaches to the assessment, forecasting and management of stability that appear with fluctuations in the external environment of the industrial enterprise functioning. On the basis of the analysis of modern scientific approaches to the quantitative assessment of the level of economic stability of the enterprise, the authors identify main requirements which are included in the methodology for the assessment of stability under conditions of variable economy.
Keywords: economic stability, financial stability, mini-economic system stability, probabilistic and statistical methods.

1. Introduction.

Management of industrial enterprise development is related primarily to the stability of its economic activity. Developing a long-term strategy aimed at achieving the set socio-economic indices should include the analysis of their dynamics and ensure the minimization of cost to perform the target. Objectively existing and essentially ineradicable uncertainty of an industrial enterprise environment causes disturbing effects in the process of moving toward the goal. The consequence of this is the need for companies to develop science-based algorithms that determine the order of assessment and forecasting of the enterprise economic stability with respect to the functioning or developing goals.

2. Latest research and publications analysis

As part of the task the scientific works of Russian and foreign scientists regarding the stability of the enterprise were considered. Among them are the works of R. Ackoff & Emeris F. (1974), G.I. Sycheva, E.B. Kolbachev & V.A. Sychev (2004), L. Howard (1960), A.V. Shmidt & T.A. Khudyakova (2015), N.S. Necheukhina (2010) and others.

However, it should be noted that currently stability is often seen as a deterministic category. At the same time, the present economic situation does not allow to identify clearly both input and output parameters of the mini-economic system. The model parameters both initial and final have a greater degree of variability, which is an especially characteristic feature of the global economic crisis. In this regard, the need to develop algorithms considering uncertainty of the enterprise environment upon its resulting indicator and ultimately the level of economic stability is growing.

3. Basic results.

The most acceptable method of forecasting the cost of the enterprise for the investor, according to many economists, is the income approach, under which the enterprise value is calculated on the basis of forward-looking indices of cash flows. However, it is important for investors not only what the gain will be and, consequently, what the expected value of the enterprise is, but also how stable such an income is. Business risks are the reason for the instability of the expected revenue from the business**.**

Further on, let us take the probability of achieving the goal as a measure of economic stability of the enterprise.

The results of forecasting the indices of economic stability of the enterprise should be used:

• when assessing the economic stability of the company and the development of measures to improve the economic stability of the enterprise;

• when optimizing production management strategies considering stability criteria;

• when planning the cost of maintenance for the economic stability of the enterprise.

According to the income approach, the value of the enterprise is determined by the cash flow, that is by the difference between all receivable and payable cash for a certain period of time:

$$C_T = \sum \frac{CF_i}{(1+r_i)^i} + \frac{CF_{n+1}}{r_{n+1} - q}, \quad (1)$$

where C_T – the value of the enterprise;
CF_i – expectation value of cash flow in the *i*-th time period (Cash Flow);
R_i – the rate of return (discount rate) in the *i*-th time period;
n – number of stages considered in the forecast period.

$$n = \frac{t_n}{t_1}, \quad (2)$$

where t_n – the time of the forecast period;
t_1 – time stage;
CF_{n+1} – the value of cash flow for the first year post-forecast period;
q – the rate of long-term cash flow growth.

Expectation of the economic stability of the enterprise is carried out in accordance with the block diagram (Fig. 1).

In the course of the enterprise functioning there may occur events (the perturbing effects of macro, meso and micro-level) $B_1, B_2, \ldots, B_k$, the probability of which are known or obtained in the determination of the initial information. B_i offensive event or several events bring the company in one of the states $S_1, S_2, \ldots, S_m$. Getting in any state is considered a random event.

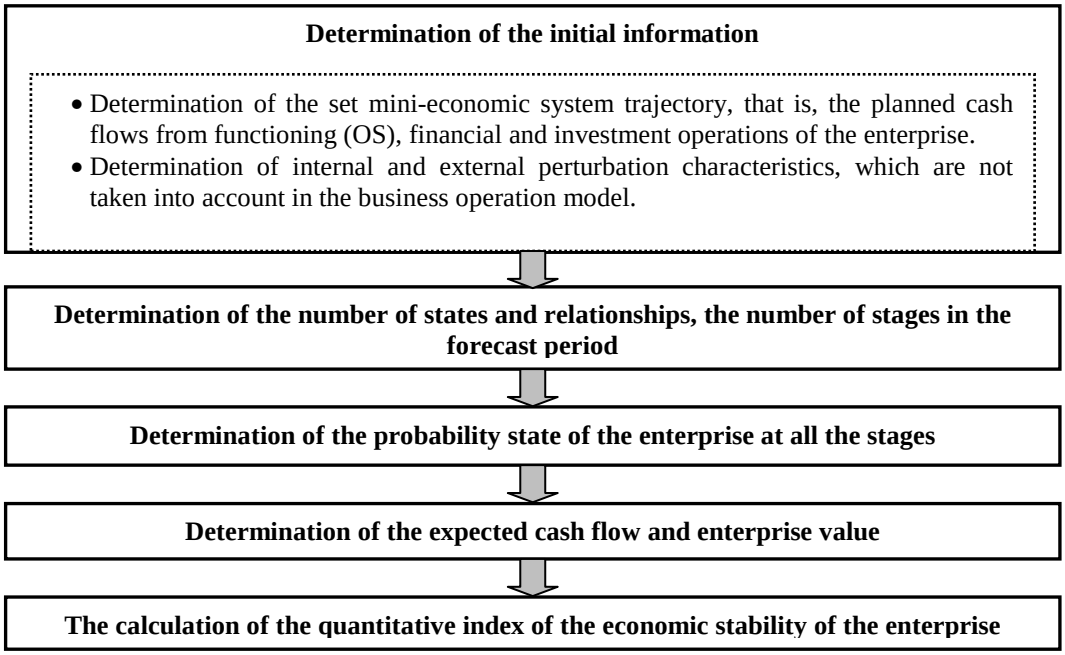

Fig. 1. Block diagram of the process of forecasting the economic stability of the enterprise

Let us set the number of companies' states and the focused weighed transition graph. The duration of stage *t* is set on the following conditions:

• cash flows of adjacent stages *CFi* and *CFi-1* must be independent;

• the probability of multiple implementations of an adverse disturbance *Bi* at the stage should be a small quantity, which can be neglected;
• the stage length must be equal or a multiple to the reporting period, adopted at the company.

The probability of the system states after the *k*-th stage is determined by the formula:

$$P_{<m>}(k) = P_{<m>}(k-1) * \Pi_{k-1,k}, \quad k=1, 2, \ldots, n, \tag{3}$$

where $P_{<m>}(k), P_{<m>}(k-1)$ – vectors of state probabilities at the *k* and *k*-1 stages;
$\Pi_{k-1,k}$ – transition probability matrix.

$$\Pi_{k-1,k} = \begin{bmatrix} p_{11} & p_{12} & \cdots & p_{1m} \\ p_{21} & p_{22} & \cdots & p_{2m} \\ \cdots & \cdots & \cdots & \cdots \\ p_{m1} & p_{m2} & \cdots & p_{mm} \end{bmatrix}. \tag{4}$$

Expected values of cash flow at the stages:

$$CF(i) = CF_1(i) + CF_2(i) + \ldots + CF_m(i) = CF_{<m>}(i). \tag{5}$$

$$CF_{<m>}(i) = P_{<m>}(i-1) * \begin{bmatrix} p_{11}d_{11} & p_{12}d_{12} & \cdots & p_{1m}d_{1m} \\ p_{21}d_{21} & p_{22}d_{22} & \cdots & p_{2m}d_{2m} \\ \cdots & \cdots & \cdots & \cdots \\ p_{m1}d_{m1} & p_{m2}d_{m2} & \cdots & p_{mm}d_{mm} \end{bmatrix}, \tag{6}$$

where $CF(i)$ – average value of cash flow in the *i*-th stage;
$CF_j(i)$ – the value of the cash flow for that *i*-th-stage in *j*-th-state considering probability based streams;
d_{ij} – cash flow value at a stage in the transition from state *i* to state *j*.

To determine the cash flow variance values at the stage we represent $CF_j(i)$ as:

$$CF_j(i) = Q_j(i) * P_j(i), \tag{7}$$

where $Q_j(i)$ –cash flow value, enterprise-generated on the *i*-th stage in the *j*-th state without taking into account the probability of the state;
$P_j(i)$ – the probability of finding the company on the i-th stage in the j-th state.

The obtained values of the random variable $Q_j(i)$, $i=1, 2, \ldots, m$ in different states of the enterprise S_j, $j=1, 2, \ldots, m$ and the corresponding probabilities of the enterprise in these states $P_j(i)$ can be represented as a series of distribution (Tab. 1) and distribution polygon (Fig. 2).

Table 1: Several cash flow distribution values $Q_j(i)$, $i=1, 2, \ldots, m$, i and the probability $P_j(i)$ of the enterprise being in S_i states

States	S_1	S_2	...	S_m
$Q_j(i)$	$Q_1(i)$	$Q_2(i)$	…	$Q_m(i)$
$P_j(i)$	$P_1(i)$	$P_2(i)$	…	$P_m(i)$

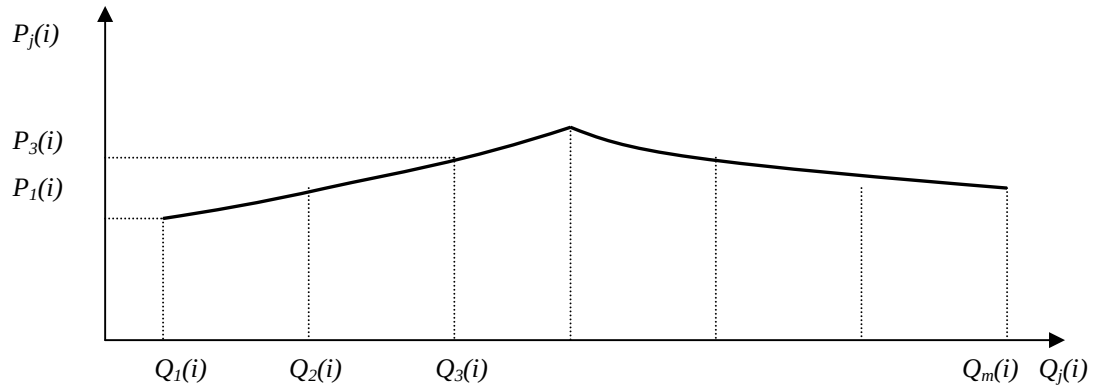

Fig. 2. Distribution of cash flow values, generated by the enterprise in step *i*

Cash flow variance values at the *i*-th stage is calculated as follows:

$$D[CF(i)] = \sum_{j=1}^{m} [Q_j(i) - CF(i)]^2 P_j(i). \quad (8)$$

Enterprise value is determined by the cash flow generated in the series of consistently considered stages. The expectation value of a company is determined by the sum of the mathematical expectations of cash flow values at n stages and post-forecast period:

$$M[C_T] = \sum_{i=1}^{n} \frac{CF(i)}{(1+r_i)^i} + \frac{CF(n+1)}{r_{n+1} - q}. \quad (9)$$

Enterprise variance value is equal to:

$$D[C_T] = \sum_{i=1}^{n} \frac{D[CF(i)]}{(1+r_i)^{2i}} + \frac{D[CF(n+1)]}{(r_{n+1} - q)^2}. \quad (10)$$

If the limit of the tolerance range value of the enterprise value is determined, then the probability of sustainability of the enterprise is:

$$P = \frac{1}{\sqrt{2\pi D[C_T]}} \int_{\Gamma_б}^{+\infty} e^{-\frac{(C_T - M[C_T])^2}{2D[C_T]}} dC_T. \quad (11)$$

If the limit of tolerance range goal is a random variable distributed by the normal law with expectation $M[\Gamma_б]$ and variance $D[\Gamma_б]$ (Fig. 3), then to determine the index of economic stability of the industrial enterprise let us introduce the random variable *G*:

$$G = C_T - \Gamma_б. \quad (12)$$

with expectation:

$$M[G] = M[C_T] - M[\Gamma_б]. \quad (13)$$

and variance:

$$D[G] = D[C_T] + D[\Gamma_б]. \quad (14)$$

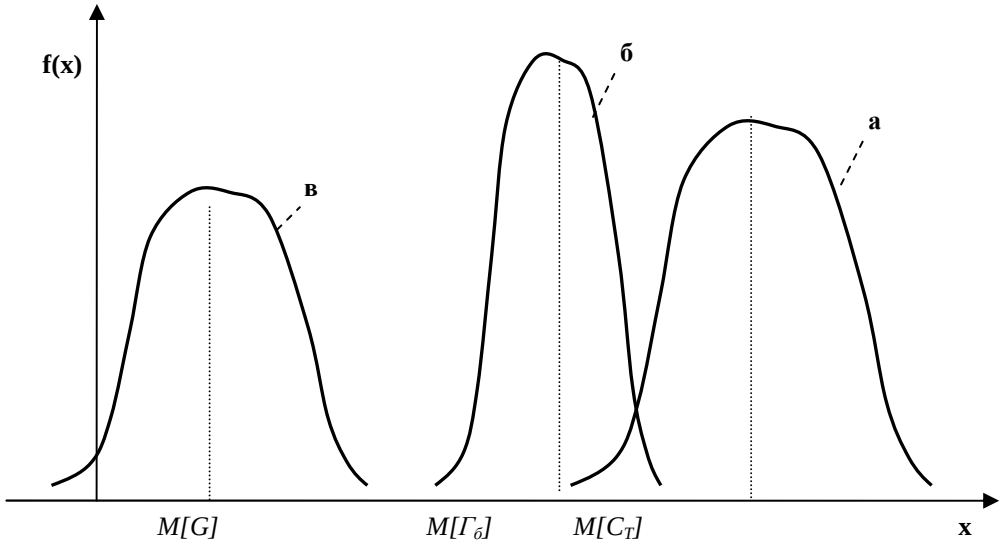

Fig. 3. Density distribution of enterprise value (a), the limits of permissible values of the target functioning (development) (b) and a random variable (c)

The probability of economic stability in this case equals:

$$P = \frac{1}{\sqrt{2\pi D[G]}} \int_0^{+\infty} e^{-\frac{(G-M[G])^2}{2D[G]}} dG. \quad (15)$$

4. Conclusions.

Thus, the task of analyzing the stability development of the industrial enterprise reduces to quantitative determination of the possibility to achieve its set cash flow increment. The proposed concept of the study of enterprise economic stability considers models of its development based on the identification of deviation risks from the trajectory. This handy research tool is a unit of Markov random processes. Its use for the analysis of the industrial enterprise discloses the possibility to determine the interdependence of the initial values of the considered risks and trajectory parameters of the target, which enables to predict the enterprise economic stability more accurately.

The Genesis of the Concept of "Economic Stability" of a Socio-Economic System

Shmidt Andrey Vladimirovich, South Ural State University (national research university), Chelyabinsk, Russia, shmidtav@susu.ru
Khudyakova Tatyana Albertovna, South Ural State University (national research university), Chelyabinsk, Russia, khudiakovata@susu.ru

Abstract:

Management of socio-economic system development is associated with its stability maintenance. The elaboration of a long-term strategy should include the analysis of the dynamics of socio-economic indices and ensure the minimization of costs to achieve the goal. Objectively existing enterprise environmental uncertainty implies disturbing influences in the process of movement towards the goal. In the terms of theoretical methodology, the issues of economic criteria selection for assessment of the enterprise' stability become urgent. The conceptual category of "economic stability" of a socio-economic system is of particular significance. The main purpose of article is consideration of modern approaches to assessing the sustainability of enterprises, identifying the distinctive features of financial stability and economic sustainability in a dynamic environment, the formation of approaches to the assessment of sustainability from the perspective of the principle of goal-setting. The analysis in the article is necessary for further development of tools for assessing and forecasting sustainability of the enterprise in a dynamic environment.

Keywords: economic stability, sustainable economic development, the probability of achieving the goal, phase trajectory.

Introduction.

The analysis of the impact of disturbances on a mini-economic system, in our opinion, must be implemented with consideration of the company as an open socio-economic system, which can be treated as a particularly complex system in the terms of Bira's classification (Ilysheva & Ilmenskaya, 2009). The specifics of functioning and development, as well as the parameters of the internal environment of open social-economic systems are dependent on the state and dynamics of the external environment. An important feature of the establishments working as open systems is noted to be characterized by high uncertainty and poor predictability of the organizational relationships nature (Peregoudov & Tarasenko, 1989).

It should be mentioned that the study of the impact of disturbing factors on enterprise mini-economic system, considered as an open socio-economic system, on the one hand, makes it possible to use the concepts and principles of the various areas of system research, with the object of study to be the laws of functioning and development of particularly complex systems. On the other hand, such study requires the development of new economic indices and system techniques to determine the level of economic viability of the enterprise to these environmental factors.

Thus, the issues of improving the efficiency of business operation in dynamic and uncertain environments are dominant in modern research. This necessitates the elaboration of new concepts of sustainable economic development and functioning of establishments, based on the synthesis of traditional economic approaches as well as natural sciences and humanities research achievements.

2. Research and publications analysis.

As part of this work, we investigated scientific researches of Russian authors in two analysis areas. The first approach concerns the stability of the social-economic systems. The second approach, subject to scrutiny, considers the theory of technical systems.

Within the first field, we studied the works by Sokolov M.D. (2000), S.S. Starikov (1999), O.A. Eliseeva (2011), Roshchin V.I. (2000), E. Winston (2014), J.K. Persky, V. Lepikhina & E.V. Semenova (2015), V.A. Kozlov & L.A. Danchenok (2012) and others.
Scientific approaches to systems analysis were elaborated by F.I. Peregudova & F.P. Tarasenko (1989), V.D. Mogilev (1999), V.I. Zarubin & R.M. Hadzhirokova (2014), I.N. Haimovich & N.M. Kuzmina (2013), L.S. Zvyagin (2014) and others.
On the basis of the analyses we can state the fact that the theory of systems is not sufficiently used in the study of socio-economic systems. However, in our opinion, despite the fact that the socio-economic system, of course, has some significant differences from a technical system, it is the application of the system analysis that can greatly contribute to assessing, forecasting and management of sustainable socio-economic systems, including businesses. In this regard, our task is, firstly, to determine the meaning of the conceptual category of "stability of socio- economic systems"; secondly, to work out clear distinction between the concept of "financial stability" and "economic stability", as the discussed works often identify these concepts; thirdly, to evaluate the possibility of application of system analysis concepts to the socio-economic systems.

3. Materials and Methods. Table 1 lists the definitions of the concept "economic stability", found in various literary sources.

Table 1: The definitions of the concept enterprise economic stability

№ п/п	Definition
1	Economic stability of the enterprise is the adaptability of enterprises to occurring or expected changes in the future (Mogilevsky, 1999).
2	Stability is the intent to equilibrium in conditions of the complete absence of vibrations or in an environment of damped oscillations (Sokolov, 2000).
3	Organizational and economic stability is understood as the company's ability to maintain financial stability in a constantly changing market conditions by improving and targeted development of its production technology and organization methods of logistics-oriented management (Alekseeva, 1997).
4	Economic stability of the enterprise is defined as a system having an internal resistance, depending on the influence of external and internal factors (Omelchenko & etc., 1999).
5	Economic stability is a state of dynamic development of the economic entity when its peculiar socio-economic parameters under any disturbances of external and internal environment preserve economic equilibrium at a particular level (Starikova, 1999).
6	Enterprise economic stability is a permanent state of the enterprise, in which its activity provides in the existing variable conditions the fulfillment of all its obligations to employees, partners and the state thanks to the balance of assets and liabilities, the creation of adequate reserves, the reduction of the risk of loss (Roshchin, 2000).
7	Economic stability is a combination of the most important elements of a business entity: industrial activity, organizational work, financial and monetary, material and technical base, resource support, human and intellectual potential, which determines the attitude of a business entity to an external environment, its interaction with economic actors of various levels, and allows to establish dynamic equilibrium comprehensive system, which independently ensures purposeful movement at present and the foreseeable future (Korshunov, 2000).
8	Economic stability is the dynamic compliance of the enterprise state parameters to external and internal environment, which ensures its operation under conditions of disturbances with maximum efficiency (Korchagina, 1981).
9	Stability is an enterprise state, in which it is able to keep the balance of its internal structure in every period of time (Okladsky, 2000).

10	Industrial enterprise economic stability is a business entity state, when its characterizing socio-economic parameters under any disturbances of external and internal environments, maintaining the original balance, are in a particular area of economic stability, the bounds of which are approved for a given period of time, while the dynamically developing (Sergeev, 2000).
11	Stability of the enterprise functioning presupposes its structural transparency and reliability, the ability to adapt to a rapidly changing economic conditions, susceptibility to innovations and is mainly achieved through the effective use of all available resources of the enterprise (Lotov 1984).

12	Economic stability of complex systems is such a state, when their cost-effective operation and sustainable development within the prescribed limits at self-financing in a dynamic environment is provided (Malinin, 1997).
13	Economic stability is a state of the construction company, with the most important organization management subsystem, adjusting the factors that determine economic growth, and return the system to a state of relative equilibrium in the new risk conditions (Kammaev, 2000).
14	Stability of the system is defined as its ability to maintain the values of essential variables within acceptable limits under various states of the environment (Mityushin, 1981).
15	Economic stability is the ability of the enterprise in a relatively long period of time to maintain and increase its own production capacity in order to keep and expand the market segment occupied (Kharchenko, 1999).
16	Stability of the system is its ability not to be subjected to fluctuations (changes) under the influence of external factors (Shevrina, 2000).
17	Economic stability of the agricultural firm is characterized by a stable growth of the final product added value, a stable position on the market, profitability of production over the industry average level, the absence of overdue debt and the size of current revenues, providing timely current payments (Mosin, 1997).
18	Economic stability is the ability of the economic system to maintain proportionality in reproductive development in order to reduce the negative effects of exposing adverse factors (Labaznova, 2000).
19	Economic stability is the ability of production and economic system to return to a stability position when there are changes in the conditions of doing business. Thus, the economic stability refers to the preservation of positive trends in the level of use of the organization production capacity, taking into account prevailing balance between supply and demand in selected strategic areas of management (Inzhinova, 1999).

The analysis of the definitions can highlight shortcomings inherent in them.

Definitions 2, 5, 7, 9 and 13 seem one-sided, based primarily on the concept of social equilibrium of the economic system, at the same time do not explain the concept itself.

Since there is no conventional economic entity balance criterion, the understanding of the concept of economic stability seems complicated. Moreover, the quoted definitions do not differentiate between the concepts of economic stability and equilibrium of the enterprise.

Similar shortcomings may characterize definitions 1 and 11, which reveal the essence of economic stability, mainly through the concept of adaptability. This concept is vague and uncertain to be quantified, which does not contribute to an adequate understanding of the economic stability phenomenon.

Definition 3 identifies the concepts of economic and financial stability. However, financial stability is only one component of overall economic stability and therefore is considered a narrower concept.

Definitions 6 and 17 reveal the economic stability in a similar way through the financial stability.

Definition 12 elucidates the concept of economic stability through the enterprise cost-effective functioning, i.e. through economic efficiency. It is obvious that the company activities can be profitable even with a decline in a market share, decrease in capacity utilization, loss of skills, etc. Such a situation is not a sign of the economic entity stability, however, it relates to definition 12. The sustainable development criterion, involved in this definition, does not imply the fact of the economic stability due to the lack of a clear quantitative index of this development.

The common failure of definitions 4, 8, 10, 14, 16 and 18 is their incompleteness to encompass the essential features of the economic stability.

Definitions 15 and 19 reveal the essence of the economic stability through the concept of the organization production capacity. As a rule, it is understood as the company's ability to manufacture products with a certain composition and technical characteristics to the maximum extent. However, even a high capacity utilization rate can not unambiguously indicate the economic stability of the company, as it is not an obstacle for the company to have a higher level of accounts payable, low levels of sales, other negative trends.

Thus, modern economic science distinguishes two significant approaches to the study of the stability of socio-economic systems: static and dynamic. The static method, which has already become traditional, examines the financial stability of enterprises as a result of financial and economic activity. The dynamic approach defines the stability of the enterprise from the standpoint of the dynamics in internal and external economic processes.

When considering the static approach, on the basis of financial and economic analysis stability is treated as a certain state of enterprise accounts, guaranteeing its solvency, i.e. the implementation of all its commitments to employees, partners and the state. Financial stability of the company is analyzed not dynamically, but at any given time. This static approach is rather objective, since the study is based on financial statements: the cash flow statement, the statement of profit and loss account, the balance sheet.

As we see it, the definition of the enterprise "financial stability" concept implies some inconsistency, which leads to its discrepancy with the traditional, conventional elucidation of the "stability" category, interpreted by the general theory of systems. Taking into account the financial and economic analysis, stability denotes mainly the company's ability to fulfill its obligations. At the same time, when considering the dynamic approach, stability, seen on the basis of system analysis (by Lyapunov), refers to the system ability to return to equilibrium under the influence of disturbing factors of the environment.

Furthermore, when considering the "economic stability" concept, it is worth mentioning that the main feature of socio-economic systems consists in the fact that they operate in accordance with the set goal. Hence, such systems can be treated as goal-oriented systems.

It should be clear that the goal is the desired state of the economic system that reflects the will of the system managing entity and has a well-defined period of existence. Firstly, the economic systems goal changes depending on the specific situation. Secondly, as the goal is characterized by some subjectivity (the goal does not appear automatically from the system operation mechanism), the system state, in which it achieves the goal, is not necessarily the optimal or at least typical of it, which is not the case with technical systems.

Thus, the special feature of economic systems is manifested primarily in the fact that they are goal-oriented, with the goals of their development not always stipulated by technological properties of technical systems, which are their constituents.

Let us call the process of setting targets “goal-setting”. Goal setting is perhaps the most important process for the economic systems. "Incorrect choice of goals in creating a system leads to the fact that the wrong problems are solved. This can lead to more serious detriment than the inefficient use of the system to achieve the set goals." Goal-setting is so important in the management of economic systems that it can be considered together with monitoring goals to be the content of process control systems.

Goal-setting provides for mandatory consideration of the studied system (organization) possibilities, as otherwise the goals will be unrealistic and look like a dream. It is due to the

comparison of the desired goals of the organization and its capabilities, companies are able to set realistic goals. In the process of goal-setting, according to American scientists, the economic systems are characterized by conservatism and inertia behavior. As a result, goals are set with great caution, taking into account the whole range of environmental conditions and experience.

Such understanding of the goal-setting mechanism is reflected in the following relationship:

$$M_i^t = f_i(M_{t-1}; U_{t-1}; N_{t-1}), \quad (1)$$

where M_i^t – the level of claims for the goal characteristic *i* in period *t*;

f_i – the goal function;

M_{t-1} – the actual level achieved in the previous period;

U_{t-1} – the level of achievement, deduced from the previous organizational experience;

N_{t-1} – the level, achieved by other economic systems in similar situations.

The information nature of the economic systems management should be considered, when goal-setting. In this connection, the correlation of the objective and the subjective in the process of administrative problems solution is of major importance. Objective reality influences the economic entity via an information system. The business entity generates incentives for targeted action to transform the goal system to the desired state (Figure 1).

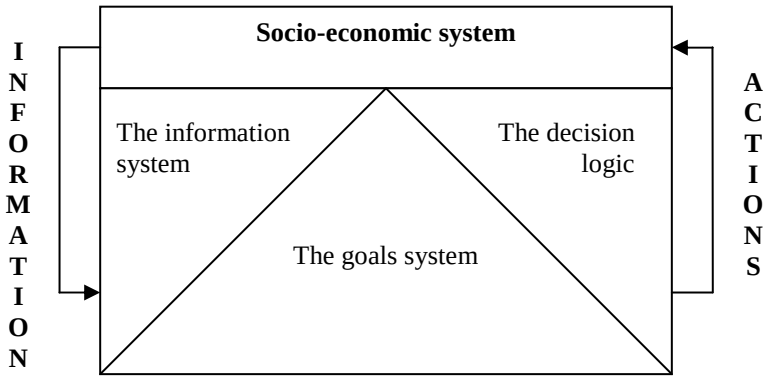

Fig. 1. The correlation of the objective and the subjective in the socio-economic systems analysis

(Source: own)

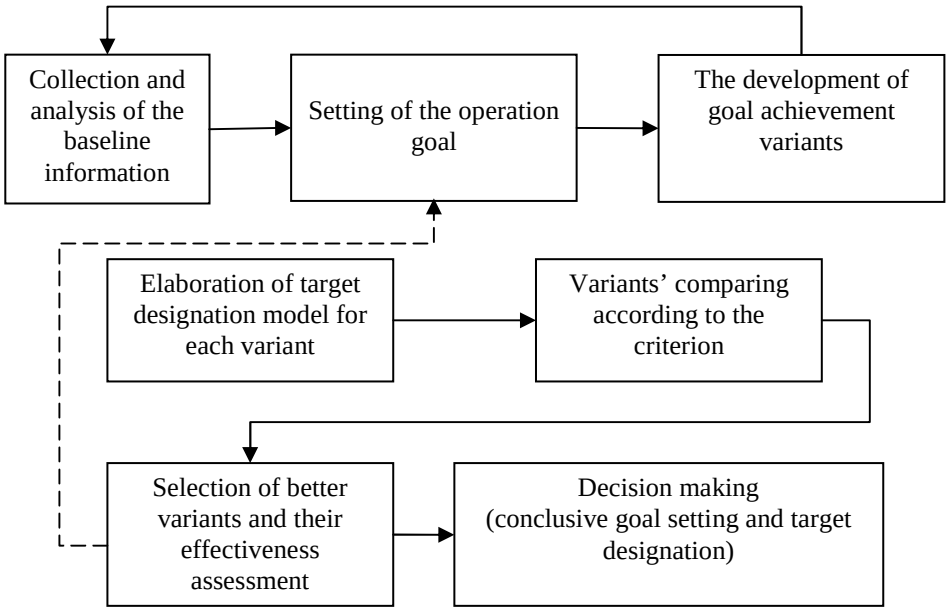

Fig. 2. Formulation of the operation goal based on the analysis of economic and mathematical model

(Source: own)

In general, you can single out the following principles of goal-setting:

• economic systems goals are based on the hypothesis of their would be development, but are determined by the present state of the economic system;

• the success of the goals system formation depends on the person responsible for the goal-setting process (in particular, his intellectual abilities); material and organizational resources allocated to achieve this goal; and the organization of the information system that supports the decision of economic systems subjects;

• valid and comprehensive information on the state of the entity and the environment contributes to the development of the proper business strategy and is critical to the successful implementation of the goals.

In reality goal setting is accompanied by target designation. Target designation is the process of formalizing the goal, presenting it through the relationship between different parameters of the system. In the process of target designation the results of goal-setting are brought to the attention of the system actuator. In contrast to the goal setting, target designation occurs in all kinds of systems (natural, technological, economic). Target designation is necessary to justify the perception peculiarities of the functional elements of the system of targets, for which the goal must necessarily be described by any parameters they can influence.

Thus, as we see it, the economic stability of an industrial enterprise, as an open goal-oriented system, is defined as the ability to achieve planned results with the specified characteristics of possible deviations that determine efficient use of resources.

It appears that stability is a fundamental feature of systems (including economic), that distinguish them from a random set of components. Stability is the ability to preserve the system features with external and internal factors changes, the ability to exist.

So, in our opinion, in the current circumstances it is necessary to examine not only the state of enterprise accounts (financial stability), but also to determine the economic stability of the enterprise in progress on the basis of particularly complex systems analysis. Table 2 presents the contents of the concepts of "financial stability» (Savitskaya, 2008; Sheremet, 2009) and "economic stability".

It appears that the stability of industrial enterprises, as an open goal-oriented socio-economic system, can be defined as the ability to achieve planned results with the specified characteristics of possible deviations, and the ability to function and develop effectively considering the set goal, despite the deflecting impact of disturbing environmental factors of various origins.

The sustainable economic development is the manifestation of the industrial enterprise ability, under the influence of disturbing factors of macro, meso and microenvironments with a high degree

of variability to achieve the development goal. The sustainable economic development is processed through certain phases, characterized by stable economic performance with an appropriate sustainability level.

A clear-cut division of the analyzed concepts can be carried out by considering them within a single space-time continuum "past-present-future." The concept of the sustainable economic operation should be viewed in the segment "past-present". Correspondingly, the sustainable economic development - in the segment "present-future."

Furthermore, the presence of stability is generally explained by the simultaneous action of two polar trends. The first deals with the reproduction and preservation of the systemic properties and qualities. The second allows the system to adapt to new conditions. Thus, we can say that the sustainable economic development is based on the principles of evolution - the preservation of identity and adaptation to the environment. Hence, the sustainable economic operation is the ability of mini-economic system under the influence of disturbing factors of the environment to preserve and restore its unique systemic features and qualities. The sustainable economic development is the example of mini-economic system functioning in complex environment with a high degree of variability of different levels disturbing factors. Such a process is characterized by the preservation and reproduction of unique systemic features and qualities together with their quantitative and qualitative transformation under the influence of the adaptation mechanism to the external environment.

Research into the dynamic functioning and developing of economic systems, as we see it, can be carried out with the use of complex systems functioning approaches. The possibility to apply complex systems sustainability principles in economics is predetermined by the fact that from a systemic point of view, all natural, technical and economic systems have similar features.

Table 2: The contents of the concepts of "financial stability» and "economic stability" treated dynamically

№ п/п	The feature analyzed	The category of "financial stability"	The category of "economic stability"
1.	Intrinsic features	State of enterprise accounts guaranteeing its solvency	The ability of the enterprise mini-economic system under the influence of disturbing factors of the environment, to function and develop with respect to the goal
2.	Functions performed	It states the excess or lack of sources of reserves and costs formation funds	1. Forecasting the development of the economic situation; 2. Determination of opportunities to increase the economic efficiency of industrial enterprise operation
3.	Performance index	Liquidity and solvency index	Economic sustainability index system interpreted dynamically
4.	Index nature	In relation to the analyzed economic activities for the period of its implementation, in statics	A momentary one, taking into account the specific economic situation of the company, characterizes the sustainability of the enterprise operation (including retrospectives) and opportunities of sustainable enterprise economic development, considering the dynamic nature of the processes
5.	Information, necessary to determine the index	Financial statements: balance sheet, profit and loss statement, cash flow statement	The system of external and internal factors that characterize the economic situation dynamically and determine the parameters of the company as an open mini-economic

			system
6.	Prognostic potential	Low, associated with the outcomes analysis (in retrospect)	High. The indices are determined via the analysis of the system of in-house processes and mechanisms in their interaction with environmental factors and their interdependence.
7.	Possibility to apply for efficiency of business operation improvement	Below average, as the determination model of liquidity and solvency indices can not be the basis for the creation of organizational and economic mechanism to change their level	High, as the economic stability indices system in dynamics is the basis to make enterprise management decisions.

Source: own.

New approaches to the study of complex systems stability include: the chaos theory, the theory of complex systems based on Ashby principle of diversity, the evolutionary theory.

The chaos theory describes the laws of development of diverse nature systems, (in terms of environmental factors variability) focusing on the chaos, complexity and self-organization; it offers methods of effective systems management in conditions of uncertainty and dynamic changes. According to the chaos theory, infinitesimal changes in the initial conditions can impact significantly the development of the entire system. The approach mentioned can be related to the socio-economic systems of macro, meso, micro and mini levels. The success of modern organizations functioning depends on understanding the hidden dynamics of the processes that underlie the apparent changes. The crucial concept of organizational management, according to the chaos theory, is the concept of leverage, justifying the significant positive changes even with minor administrative actions. In the process of dissipative chaos, even small changes in the initial parameters of the system state lead to significant differences in the final results. Consequently, the study of organization's performance dependence on the initial conditions leads to one of the major notions of the chaos theory - the analysis of such a complex systems feature as self-organization. The chaos theory application explains the low efficiency of many techniques, used to improve the sustainability of the organization in a dynamic and uncertain environment. The same refers to the methods of the quantitative assessment of risk, based on the analysis of isolated productive operating indicators of a company.

The general systems theory investigates the issues of self-preservation and sustainability of complex systems. According to Ashby principle of diversity, the diversity of system responses must correspond to a plurality of external anti-entropic impulses. Herewith the system structure flexibility should match the level of innovation activity. If the initial stage of self-organization is characterized by external environment replication, then the system evolves towards a stable state with minimal production of entropy. Thus, the stability of the internal environment development and in-house processes is determined by the peculiarities of the external environment.

Applying the theory of systems to economics, it is necessary to consider the economic system as something organic, adaptive, and self-organizing. Currently, the following general characteristics of the most successful complex adaptive self-organizing systems can be singled out. Firstly, such systems are self-managing. Secondly, self-management is possible due to the presence of a certain feedback from the external environment. The ability of the managerial level to identify the information received is the basis for the development, adaptation and preservation of such systems. Thirdly, self-managing through the feedback allows such systems to work through mobile specialization. These mechanisms of active development sustainability are at the heart of innovation management.

In addition to the chaos theory and the general systems theory discussed above, the biological evolutionary theory is likely to be applied to socio-economic researches. The basic principles of evolution - the preservation of identity and adaptation to the environment - operate in the economy as

well. Herewith the economic entity evolves on several levels (units of evolution). The basic principle of the evolution theory is the ability of every active unit of evolution to specify its own laws, which generates closed operation, leading to the formation of identity. So, evolutionary process is the preservation of identity and the ability to adapt, which is associated with natural selection. Identity and adaptation principles can be related to the formation and preservation of the distinctive organizational features and properties of the systemic product (competitive advantages). These notions are the main object of study in marketing and strategic management.

The tendency to apply analogues from the sphere of the biological theory of evolution to other areas is the basis of the population ecology developed by foreign researchers. This approach considers intraorganizational evolution, according to which the variability of the system should be as high as possible in order to completely take into account the complexity of the dynamic changes in the environment. They point out the so-called limits of variability characterizing the most appropriate level, as defined in the general theory of systems by the relationship between uniformity and diversity of the system structure elements. To describe the adaptive ability to the changing environment in organizational studies the term "economic mimicry" is used which is identical (in the general systems theory) to the principle of conditionality of rational management effects. According to the evolutionary concept, the use of the principle of multi-level organization construction allows to develop practical approaches to determining the stability of the system. It is believed that any system evolves simultaneously on several external and internal levels which are in interactive relations with each other.

It is worth mentioning that while considering the enterprise economic stability, we should take into account a variety of interactive performances on external and internal levels of enterprises activity. That leads to the integration approaches to strategic enterprise development (Eliseeva, 2011). This multilevel principle, used in the evolutionary theory, is closely linked to George Forrester approach to elaborating simulation models of production facilities.

The evolutionary theory is widely employed in elaboration of competitive advantage strategy. According to JF Moore theory of entrepreneurial ecosystems, to ensure company’s long-term success in the market both competition and cooperation are equally important, i.e. the evolution and interdependence. Hence, instead of making unilateral competitive advantages of the company it is necessary to consider it as an element of the ecosystem, where interests of all the participants and members of the business community are linked together. Thus, there appears the phenomenon of "co-evolution".

Considering the evolutionary concept, it should be noted that the logic of evolutionary development of macroeconomics in general, the stage of a particular industry or region development, the age of the individual areas of economic activity determine together the most efficient combination of external and internal factors of the enterprises sustainable state in this economic time interval.

Conclusion.

As we see it, the data discussed in the article gives reasons to conclude that modern economics has sufficient theoretical tools to study the dynamics of transient economic processes in mini-economic systems. At the same time, the evolutionary principles synthesized with the general theory of systems can be applied to explain complex phenomena in mini-economic systems. The knowledge symbiosis will enhance the accuracy of the assessment, forecasting and management of socio-economic systems. This fact will serve as a prerequisite to improve the economic stability of the system.

Abstract

Consumer behaviour can be seen in several ways and in many areas of our lives. It depends on many factors in the broader context of changing consumer behaviour. Paper deals with consumer behaviour in selected tourism sector. At example of place of purchasing the holiday products influencing travellers' decision when buying holiday in their free time and factors influencing their decision making it shows partial results of the survey at the sample of selected town. The goal was to identify, evaluate and describe the behaviour of tourism when choosing travelling options based on the realized questionnaire survey.

Keywords: consumer, tourism, behaviour, tourists, marketing tools.

Introduction

Consumer behaviour always changes. There is no other situation in tourism sphere. Travellers are more experienced, globalised world brings more possibilities, fast means of transport can bring us to distant destinations in shorter time, internet brings us immediate information about different place, people share their experience etc. and that´s why it is always important to survey the market and the changes at it. Consumer behaviour of tourists depends on many factors that might influence decision making before travelling and choosing the destination. The article tries to show results of consumer behaviour survey held in chosen town and its partial results.

Literature review

The definition according to the American Marketing Association (AMA) mentioned in Richter et al. (2005, p. 9) says that "consumer behaviour is a dynamic interaction of humans and the environment contain emotions, knowledge and actions through which people carry out the exchange in order to meet their needs. In other words, consumer behaviour has the cognitive, affective and conative component that means that it involves thinking, feeling and actions of people they do in the context of the consumption process. " Morrison in 1995 stated that "consumer behaviour is a way how customers choose the services purchased and consumed and their behaviour after their purchase" (Morrison, 1995, p. 71). This shows that it is a behaviour that is reflected throughout the process of purchasing decisions. The same understanding for this topic had Schiffman and Kanuk (2004, p. 14), who defined the purchasing behaviour as "behaviour to show consumers in finding, purchasing, use, evaluation and management of goods and services, which hopes to meet their needs."

In terms of complexity consumer behaviour is the study of a process where consumers acquire, consume and dispose of goods, services, activities and ideas in order to satisfy their needs and desires. Consumer behaviour is and always will be influenced by satisfying needs. On consumer behaviour and choice when purchasing operate the whole complex of factors that marketing is not able to influence (cultural, social and personal factors) and psychological factors, which are only partially modifiable (Richter 2005 Bačík, Štefko, Gburová, 2015). When analysing purchasing

behaviour it is essential to understand why people make purchases, what factors influence them when and how those factors change in our society. Marketers need to know the factors that influence consumer behaviour, how they work and how to better understand them, to better fill up to the expectations of consumers and improve their marketing strategies.

Armstrong and Kotler in 2004 clearly named 4 main types of factors that influence consumer behaviour. Those are: cultural factors, social factors, personal factors, psychological factors. Richterová (2007) modified mentioned factors into: socio-cultural factors, social factors, individual factors and psychological factors. As socio- cultural factors she mentioned culture, sub-culture and social status. In social factors she mentions family, life cycle, reference groups and influential people. Individual factors she perceives as employment, income, personality, values and lifestyle. The last psychological group includes motivation, perceiving, studying and attitude. Cibáková a kol. (2008) states that the result of factors affecting consumer buying behaviour is that the consumer is more experienced and sensitive to price and still more complicated in lifestyle, calls for greater comfort when buying, has higher demands for quality, reliability and performance of products and exhibits less loyalty to the supplier. In principle it is possible understand the statement that consumer behaviour consists of actions that people perform in buying or using products and services, including mental and social processes that precede these activities and follow them. Richterová et al. (2007) states that these processes occur: 1. Prior to the purchase itself - eg. awareness of the need, the choice of shops, product, 2. after purchase - Utility Rating and 3. after purchase - evaluation of usefulness. In the process, it is necessary not to forget information that protrudes consumers with the product at all these stages. The information is in today's world the key factor, not only for businesses but also for consumers. Timely collection of information and its correct interpretation and usage is for business a significant competitive advantage. Customers as potential customers give great emphasis on the timeliness, accuracy and comprehensiveness. Most of them are based on information available decide on the purchase of goods and the use of services (Širá, Radvanská, 2010).

Methods and methodology

Based on this theoretical background was the aim of the present paper, based on a survey carried out by consumer behaviour in the sphere of tourism. The paper aimed to identify, evaluate and describe consumer behaviour in tourism sphere at the example of consumer behaviour concerning the place of purchase and factors influencing the consumer decision when buying certain travel possibilities at the example of chosen town and its inhabitants.

The original questionnaire consisted of 20 questions. For the purposes of this paper were selected only some of them focused on factors influencing tourists behaviour when buying tourism products as well as the place where they but the mentioned product to spend their holiday. Obtained data from the questionnaire were processed in MS Excel and Statistica- statistical program.

Basic characteristics of respondents were performed using standard methods of descriptive statistics. Quantitative variables we expressed by average, standard deviation (SD), minimum, maximum and median values. The qualitative (categorical) variables were expressed by absolute and relative abundance and display the contingency tables or graphs. Comparison of differences between groups of respondents was processed using the Chi-square test of independence. This test based on the pivot table examines the relationship of the two quality characteristics, denoted the A (p levels r) and B (with levels). The null hypothesis of the test is the assumption of independence characters A and B. An alternative hypothesis is the opposite: the characters A and B are not independent. The test statistic has the form: $\chi^2 = \sum_{i=1}^{r}\sum_{j=1}^{s}\frac{(n_{ij}-e_{ij})^2}{e_{ij}}$, where n_{ij} are observed frequencies, $e_{ij} = \frac{n_{i.}n_{.j}}{n}$ are theoretical numbers of characters and character A level i and the character B at level *j*. The test statistics has on the level of null hypothesis asymptotic chi-square distribution with *(r-1).(s-1)* degrees of independence (Litavcová 2012). Statistically significant, was determined the significance level $\alpha = 0.05$.

Results and discussion

Partial results of the questionnaire survey were based on hypotheses that claim that Internet shopping in tourism depends on the age of the customer and that purchase over the Internet in tourism is independent of the gender of the customer.

After finishing survey data collecting 324 respondents questionnaires we included in the processing-(age of respondents from 18 years to 72 years), of which 52% were women and 48% men. Gender proportion is available in Table 1. The average age of respondents was 43.3 years (SD 14.9), the median age was 40 years. The age structure could be seen in table 2. Age structure of men and women was considered as identical (Chi-square test of independence, $p = 0.769$). There respondents were inhabitant of the town Prešov, which is considered as the third largest town in Slovakia and its total population is oscillates around 90 thousand.

Table 1 : Proportion of respondents- gender

Options	Frequency	Percent	Valid Percent	Cumulative Percent
men	156	48	48	48,0
women	168	52	52	100,00

Source: own processing

Table 2: Proportion of respondents- age

Options	Frequency	Percent	Valid Percent	Cumulative Percent
18-25 years old	34	11	11	11,0
26-40 years old	126	39	39	40,0
41-60 years old	114	35	35	75,0
61 and more	50	15	15	100,0
Σ	324	100	100	x

Source: own processing

5% of survey responded were primary educated respondents, 23% respondents with finished secondary school without graduation, 39% with upper secondary education, and 33% respondents with university degree. 17% of women and 41 % of men were secondary educated without graduation. Women responded in the survey were higher educated than men (chi-square test of independence, $p < 0.001$). 44% of women and 21% of men were university graduated. 61% of the interviewed people were employed, 16% retired, 13% self-employed persons, 5% unemployed people and the same number of students (5%).

For the need to create more complex perspective on the issue of a sample was heterogeneous. Aim was to reach the widest possible range of respondents in each category. Respondents do not constitute a random sample to be in each category represented roughly proportionally.

The first chosen question was question concerning the place of purchases. The aim was to find out what kind of purchase the respondents in different categories and different age and social status prefer when buying holidays. The question was clearly stated and selected only for travelling in free time as holiday travel, not the working one. Three possibilities were offered for the response. The assumption was that the interest of buying holiday through internet increases. The other possibilities were traditional travel agencies stated as stone shops as well as tourism fairs.

Table 3 : Place of the purchases

Options	Frequency	Percent	Valid Percent	Cumulative Percent
Shop (stone)	266	82,1	82,1	82,1
Internet	46	14,2	14,2	96,3
Fairs	12	3,7	3,7	100,00
Σ	324	100	100	x

Source: own processing

From the results in Table 3 cold be seen that the expectation that internet shopping seems to be increasing in this case of mentioned town wasn´t true. Still preferred are "stone" shops of travel agencies. The reason why people still prefer it is still the immediate communication, proper advice services as well as habit to do it as before. Other preferences are based on the fact that travellers like to visit and buy product of travel agencies that they travelled before and have good experience with. The minority of respondents choose the possibility of buying product when different tourism fairs are held. This occasion also brings possibility to communicate with tour operators, to see all possibilities and have a little taste of it, because it´s usually connected with presentation of the local specialities. Internet is becoming more and more popular but in this case travellers must rely on their own judgment or on the other hand on reviews, which may not be true.

Table 4 : Location of the purchases on the basis of gender

n_{ij} / e_{ij}	men	women	
implements Internet purchases	13 / 11,1	10 / 11,9	χ^2= 0,753 p = 0,386
Don´t implement Internet purchases	65 / 66,9	74 / 72,1	

Table 5 : Location of the purchases on the basis of age

n_{ij} / e_{ij}	Up to 40 (years)	over 40 (years)	
implements Internet purchases	18 / 11,4	5 / 11,6	χ^2= 8,943 p = 0,003
Don´t implement Internet purchases	62 / 68,6	77 / 70,4	

Table 6 : Purchase in shops (stone shops) by age of respondents

n_{ij} / e_{ij}	Up to 40 (years)	over 40 (years)	
Buy in-store	61 / 68,1	77 / 69,9	χ^2= 9,999 p = 0,002
Don´t buy in-store by age of respondents	19 / 11,9	5 / 12,1	

Source: own processing

Results linked with variables could be seen in table 4,5,6, where location of the purchases on the basis of gender, Location of the purchases on the basis of age and Purchase (stone shops) by age of respondents were statistically evaluated.

The other question chosen for the purpose of this article a partial survey result was importance of purchase factors when buying holiday. While the town suffers long time from high unemployment rate the expectation was that price will play the most important role. Results are projected in Table 7.

Table 7 : Important purchase factors

Options	Frequency	Percent	Valid Percent	Cumulative Percent
Price	154	47,6	47,6	47,6
Quality	93	28,7	28,7	76,3
Discount	39	12	12	88,3
Review	31	9,6	9,6	97,9
Brand	7	2,1	2,1	100,0
Σ	324	100	100	X

Source: own processing

The most important factor influencing the consumer behaviour when buying a holiday was as expected price. The majority of respondents marked this possibility as the one that influences their decision making and buying. Quality of the product was chosen on the second place. Discount on holiday package seem s to be important as well. The results linked with respondents´´ variables are displayed in Table 8, 9, 10, 11, 12, 13. In virtual market reviews often play important role when hesitating and choosing holiday. While there were not many fans of internet holiday shopping, the results for review were at low level. Almost not important was the brand of travel agency. The price covered even agencies with great reputation. It is necessary to mention that respondents could choose only one possibility. For this question it was not possible to choose more options to see the preferences.

Table 8 : Importance factor in making purchasing decisions – Review

n_{ij} / e_{ij}	Up to 40 (years)	over 40 (years)	χ^2= 4,226 p = 0,040
review – important factor	13 / 8,9	5 / 9,1	
review – not important factor	67 / 71,1	77 / 72,9	

Source: own processing

Table 9 : Importance of the factor in making purchasing decisions – Brand

n_{ij} / e_{ij}	Up to 40 (years)	over 40 (years)	χ^2= 8,260 p = 0,004
brand – important factor	14 / 8,4	3 / 8,6	
brand – not important factor	66 / 71,6	79 / 73,4	

Source: own processing

Table 10 : Importance of the factor in making purchasing decisions – Price

n_{ij} / e_{ij}	Up to 500 €	500 € - 1 000 €	over 1 000 €	χ^2= 7,315 p = 0,026
price – important factor	48 / 40,9	30 / 32,0	7 / 12,1	
price– not important factor	30 / 37,1	31 / 29,0	16 / 10,9	

Source: own processing

Table 11 : Importance of the factor when making purchasing decisions - quality, taking income into account

n_{ij} / e_{ij}	Up to 500 €	500 € - 1 000 €	over 1 000 €	χ^2= 15,585 p < 0,001
quality – important factor	24 / 36,1	35 / 28,2	16 / 10,6	
quality – not important factor	54 / 41,9	26 / 32,8	7 / 12,4

Conclusion

Consumer behaviour changes and will change also in the future. It depends on various factors that play important role in decision making. There is no difference in tourism sphere. Tourists and their personalities change thanks to experience, possibilities, open free market etc. From statistically evaluated data on conducted survey at the example of chosen town it is possible to come to several conclusions. The first one is that in this case it is interesting to keep traditional stone sops of travel agencies for their consumers. Inhabitants of this small town prefer personal contact with professionals who know their offer well. Internet possibilities are faster spreadable, but for this sample don´t play such an important possibility as personal contact in travel agencies they know. From the point of the factors it is necessary to set the pricing policy to attract most potential clients. In this case discount can play interesting marketing tool in the attractiveness. Quality of the products might be important as well but from the point of economic status of inhabitants' it´s on the second place. There are also differences from the point of age, gender, education, working status, income and the other factors.

This article is one of the partial outputs under the scientific research grant VEGA 1/0857/15 "Research of economically significant factors of perception of reputation and its dominant contexts in relation to the success in the processes of e-commerce and e-marketing on the Slovak Virtual Market."

Simulation for Decision Making: The Need for Multi-Paradigm Approaches

José Luís Pereira, Universidade do Minho & Algoritmi, Guimarães, Portugal, jlmp@dsi.uminho.pt
Marco Ribeiro, WeDo Technologies, Braga, Portugal, marco.ribeiro@wedotechnologies.com

Abstract.

We are surrounded by complexity and uncertainty that constrain our ability to learn and understand the systems around us. We need tools that allow us to deal more effectively with complexity in order to be able to make better decisions. Simulation is such a tool. It provides the means to experiment and learn from observed behaviour. Simulation can be used to effectively support the evaluation of complex scenarios, however its effectiveness is deeply rooted in the ability to build models that capture all the relevant details and dynamics of a complex system. Several approaches to simulation exist, however we believe that adopting a single simulation approach may prove limiting. In this paper we argue that, in more complex situations, a multi-paradigm simulation approach, in which more than one simulation paradigm is used to study the same reality, may be a better approach.

Keywords: Multi-paradigm Simulation, Discrete-Event Simulation, System Dynamics, Agent-Based Simulation

1. Introduction

We live in a world of complex and dynamic systems. These dynamic systems pose a significant challenge to our ability to understand and transform them. We need tools that allow us to better learn about systems, manage complexity and uncertainty in order to improve our capacity to take effective decisions. We believe simulation is such a tool.

Simulation facilitates the evaluation of complex scenarios and might be the only option when it is infeasible to test them in the real-world. Simulation is perhaps the only way to discover how a complex system really works (Sterman, 2004).

Simulation works by building models of the real-system and then experimenting with them. When conducting a simulation study the first step is to build a model that mimics all the important dynamics of the real-system. In order to be able to make effective decisions we have to ensure that the simulation model is valid and reliable. This implies that all the relevant details to the decision should be included in the simulation model. After the simulation model is developed and validated one can start to experiment with it. Experimentation is accomplished by running the simulation models with different sets of parameters and observing how the system behaves accordingly. Experimentation allows one to test different scenarios and foresee the consequences of its implementation in a controlled environment, without disturbing the real world (see Fig. 1).

Simulation can be used as an effective tool for complex decision-making processes; however its ability to provide the decision-maker with quality information is directly linked to the quality of the simulation model. Quality here means the ability of the model to reliably mimic the dynamics of a system.
Usually, when building a simulation model one adopts a certain simulation approach. From all the simulation approaches three stand out as the most important ones (Meyer et al., 2009): discrete-event simulation, agent-based simulation and system dynamics. Each of these simulation approaches provides the modeller with a distinct set of constructs and a specific philosophy to modelling. In spite of established practice consisting of adopting a single simulation approach we argue that a multi-paradigm approach to simulation may reap additional rewards.

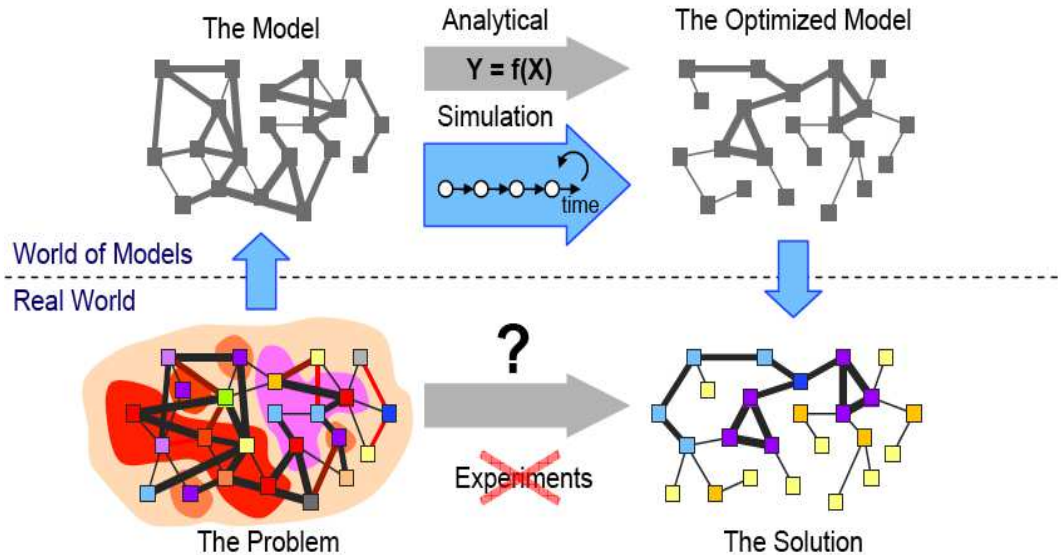

Fig. 1 – Simulation versus experimentation in the real world (Borshchev and Filippov, 2004)

By multi-paradigm simulation we mean the adoption and use of more than one simulation approach to analyse the same reality, in a complementary way. We believe that multi-paradigm simulation provides better insight into a problem by allowing its analysis from different perspectives (Scholl, 2003). Fortunately, a new wave of simulation tools makes the adoption of multi-paradigm simulation easier (Borshchev, 2007; Pegden, 2008), however there is a lack of guidelines on how to choose the simulation paradigm, or combination of simulation paradigms, that best fits the characteristic of the problem at hand. We believe this is a very important area demanding further research.

This paper is a complement to a previous one, in which we tried to clarify, the context and importance of multi-paradigm simulation utilization (Ribeiro and Pereira, 2014). To do so, after providing a high-level overview of the three simulation modelling paradigms, we present the concept of multi-paradigm simulation and we briefly describe several comparative studies of simulation paradigms that show how distinct paradigms relate to each other and how they perform when applied to the same reality. We conclude by reinforcing the need to adopt multi-paradigm simulation, especially when complex systems have to be studied and explored.

2. Simulation Paradigms

Regarding simulation, nowadays, there are essentially three simulation paradigms in use: Discrete-Event Simulation (DES), System Dynamics (SD) and Agent-Based Simulation (ABS). In the next sections, a brief characterization of each one is made.

2.1 DES Simulation

To build a simulation model the modeller adopts a simulation paradigm. From all the simulation modelling paradigms Discrete-Event Simulation (DES) has become the most widely used (Robinson, 2004). DES has been applied to study problems in areas as: organizational design (Clay, 2000), business process management (Bridgeland and Becker, 1994), decision-support (Greenwood et al., 2005), among many others.

When creating a model of a real system the modeller adheres to a certain conceptual framework, also called a worldview. A worldview is a structure of concepts and views under which the practitioner is guided in the development of a simulation model (Balci, 1988). The most used worldview is the transaction-flow worldview, in which the DES approach is the most widely known example. In this

worldview a system consists of discrete units of traffic (transactions) that compete with each other for the use of limited resources while moving (flowing) from point to point in the system (Schribber and Bunner, 2008).

A DES model is one in which the state of the modelled system changes only at discrete, but possibly random, points of time known as events. Between events the system state remains constant. The state of the system is defined as the set of variables needed to describe it at any point in time (Banks et al., 2001).

Concepts in DES modelling

A DES simulation model is built around the following set of core concepts: entities, events, resources, control elements and operations (Schribber and Bunner, 2008). DES software packages implement all of these concepts but sometimes use a different nomenclature.

Entities

An entity is any object or component in the system, which requires explicit representation in the model; examples of entities are: a customer, a machine, and a server (Banks et al., 2001). An entity can take actions that change the system state. Each entity can have its own set of properties, called attributes. Entities initiate and respond to events as they flow through the system. An event is an occurrence that changes the state of a system, for instance the arrival of a new customer (Schribber and Bunner, 2008; Banks et al., 2001). The behaviour of the system is reproduced by the execution of a pre-defined or random list of events.

Events

An event is an instantaneous occurrence that changes the state of a system (Ingalls, 2008). For example, in a simulation of a shop the arrival of a new customer is an event. An event is generated for a specific point in time, it could be the current time or a future time; when an event is scheduled to occur in the future it is registered in a structure named future event list.

Resources

Resource represent elements of a system that provide a service (Banks et al., 2001), for example in a manufacturing system machines, machine operators, transportation devices are resources. Resources are limited in number and entities compete with each other for the use of the system resources. When an entity wants to use a resource but the resource is already being used then entities must wait for their turn in a queue. A queue is an organized list of entities; entities in a queue may be sorted by priority, time of arrival, or any other criteria relevant for the model.

Control elements

Besides entities and resources, a DES model may contain control elements. Control elements support various control-related aspects of a system's state. One example of a control element is the switch; a switch is a two state variable. For example, in a model of a bank branch a switch may be used to signal if the branch is open or closed. Another control element are counters; counters may be used to count how many times a machine has been used and when a certain threshold is reached an alert for maintenance is generated. Arithmetic expressions may be used to control the operation of the system; in this case decisions are made when a certain arithmetic computation reaches a certain value; for example deciding to open a new checkout lane for customers when the average number of customers waiting is above five. The last control element are Boolean expressions; in this case decisions are made based on truth-valued expressions.

Operations

An operation or activity is a step or action carried out by or on an entity while it is flowing through the system (Banks et al., 2001). In an inventory management system the picking of goods from the

store is an example of an operation. Several operations may be ordered and combined in an integrated sequence of steps named operation logic; operation logic allows modellers to describe complex sequences of actions. An operation typically represents a period time and its duration may be specified in a number of ways: *deterministic* in this case the duration is predefined and never changes; *stochastic* where duration fits a certain statistical distribution; or it could be the result of a function.

2.2 System Dynamics

Jay Forrester at the MIT developed the System Dynamics (SD) approach in the 1960s and since then it has been used to address some of the most difficult strategic problems at companies and government agencies (Mayo and Wichman, 2003). Over the last decades, SD has been applied successfully to solve a diverse set of complex problems; for example SD has been applied to business and market modelling (Mayo and Wichman, 2003), healthcare (Brailsford, 2008), corporate strategy (Lyneis, 1994), forecasting service demand (Lyons et al., 1997), among others.

The SD vision of the world is deeply grounded in system thinking. The world is made of complex systems and in order to improve our decisions we need to be able to understand these systems. We study, understand and decide as a consequence of learning. Learning is the process of perceiving reality, making decisions that alter the real world, gather feedback information and revise our understanding of the world. Learning is a continuous feedback process of self-improvement, however there are barriers to learning.

Learning about the real world is not simple because of the dynamic complexity of the systems, limited access to information and limited capability to process and understand information. Dynamic complexity is property of a system that makes forecasting its behaviour an extremely difficult and error prone activity. We need tools to support our learning and to deal with complexity; we need tools for thinking (Pidd and Robinson, 2007). SD is a perspective and a set of conceptual tools to enable us to understand the structure and dynamics of complex systems; SD is a tool for effective decision-making and learning.

Concepts in SD modelling

SD takes on a holistic and high-level view of a system. This modelling approach allows the representation of the key performance drivers and their interdependencies within a complex dynamic system. The SD paradigm asserts that the system behaviour is caused by its structure and the structure of any system may be modelled as a set feedback processes, nonlinearities, time delays, stocks and flow structures (Sterman, 2004).

When building a SD model one should master and understand the following elements of this methodology: feedback and feedback loops, time-delayed responses, non-linear responses, stocks and flows. The behaviour of a system arises from its structure. The structure of the system consists, basically, of feedback loops, stocks and flows (Sterman, 2004).

Feedback and Feedback Loops

SD modelling starts by identifying the underlying factors that drive the behaviour of a system. This is represented as cause-effect relationships, also named feedbacks. Most complex system behaviours arise from feedback among components and not from the complexity of the component itself. Feedback have a polarity that identifies how a cause affects its dependent variable. A positive feedback means that the result changes in the same direction (increase/decrease) as the cause, and a negative feedback means that cause and effect change in different direction. For example, the price/sales feedback is a negative one because if price goes up this makes the product less affordable resulting in a decrease of sales.

Stocks and Flows

Stocks and flows, along with feedback, are the two core concepts of SD. A stock is an accumulation, which characterizes the state of the system and generate information upon which decisions are based on. Stocks provide memory to system and also create inertia; a stock causes delays in system operation by accumulating the difference between the inflows and outflows. Stocks are an abstract concept representing things that are accumulated in a system; examples of stocks are the number of people employed by a business, the inventory of products in a warehouse, the population of a country or region. Stocks are altered by flows; an inflow is a flow that increases a stock while an outflow is a flow that decreases a stock. The rate of change of a stock is determined by difference between inflows and outflows. The rates of change of the inflows and outflows are determined by differential equations.

2.3 Agent-Based Simulation

Agent-Based Simulation (ABS) is a new approach to modelling systems comprised of autonomous and interacting agents. The underlying principle of ABS is the notion that global behaviour of a system arises from the interaction of their simpler components - the agents; when building an ABS model one is not concerned with the global dynamics of a system but rather with the rules that form the agents' behaviour. According to Sanchez and Lucas an ABS simulation is a simulation made up of agents (objects or entities that behave autonomously). These agents are aware of and interact with the environment through a set of internal rules for decision-making, movement and action (Sanchez and Lucas, 2002).

This new modelling paradigm provides a new and useful approach to model complex systems that may not be modelled effectively with more traditional modelling paradigms. ABS promises to have a great impact on business decision-making processes and also on the way researchers use computers to support their research. Some have even labelled ABS simulation as a third way of doing science besides inductive and deductive reasoning (Macal and North, 2005).

Interest in ABS modelling and simulation is increasing and its applications are becoming widespread; the first reasoning driving the growing adoption of ABMS is the need to analyse and model increasingly complex systems in terms of their interdependencies, this means that traditional modelling approaches are not applicable; a second reason is that some systems have always been too complex to be adequately modelled without incurring in oversimplifications; a third reason is the increasing availability of finer-grained data organized in databases; and a fourth and last reason is the fast pace of evolution in computational platforms making feasible more complex ABS simulations (Davidsson et al., 2007).

Concepts in ABS modelling

An ABS model is made of several agents that have unique behaviour and interact with each other on an environment in order to fulfil their own goals. The global behaviour of the system will emerge from the interaction of the community of agents. ABS is rooted in complex adaptive systems and the underlying notion that systems should be built from the ground-up. In contrast with DES and SD, which take on a top-down view, ABS adopts a bottom-up approach to system modelling (Borshchev and Filippov, 2004). There are two core concepts in ABS simulation, the concept of agent and the concept of environment.

Agents

Although there is not a global and accepted definition of what an agent is, definitions tend to agree on more points than they disagree. We adopt Macal and North (2006) definition of and agent: an agent is a discrete and identifiable individual with a set of characteristics and rules governing its behaviours and decision-making. An agent is autonomous and self-directed and “lives” in an environment where he looks to achieve its own goals. Agents are flexible and may adapt their behaviour through learning and experience.

Environment

Environment is the space where agents live and interact with each other. The environment constrains the agents. For instance obstacles in the environment may limit the movement of an agent in space.

When developing an ABS model we focus on the specification of the behaviour of each agent. The behaviour is a set of rules governing the way an agent interacts with other agents and the environment, how he adapts to the changing conditions of the environment and how he makes decisions. The simulation starts be setting up an initial population of agents and let them evolve over time, the observation of this community of agents will bring out the behaviour patterns of the system.

3. Multi-paradigm simulation

Simulation is a tool to study and solve problems of real-world systems. We use simulation to improve our knowledge of how a system works and analyse the consequences of different policies, thus helping the decision-making processes. However, conclusions drawn from a simulation study are only valid if the model used represents with sufficient detail the system under investigation. It is therefore important to be able to capture all the important details and build a valid and capable model. Unfortunately, real systems are sometimes so complex that using a single simulation paradigm may imply over simplifications, with severe consequences in terms of the conclusions drawn. It is a fact that most simulation applications developed so far have followed this path. Nevertheless, we believe that, in more complex situations, multi-paradigm simulation might be the most adequate approach.

A multi-paradigm approach to simulation is needed (Borshchev and Filippov, 2004). Multi-paradigm simulation means the use of more than one modelling paradigm to study a system; different modelling techniques may be used complementarily to provide deeper insight (Scholl, 2003).

Behind each simulation paradigm is a “simulation school” with a different approach to modelling a system; each one has its own community of practitioners and its fair share of successful applications in real-world projects. These simulation communities have produced vast bodies of literature and research with over-lapping fields of applications. We believe that it is long overdue the cross study of the simulation paradigms, as they may complement each other, providing better insight. Indeed, if some business situations might be approached using one of the three main simulations paradigms - DES, SD or ABS - there are others which might be more accurately studied by using a multi-paradigm approach - DES & SD, DES & ABS, SD & ABS, or even DES & SD & ABS (see Fig. 2).

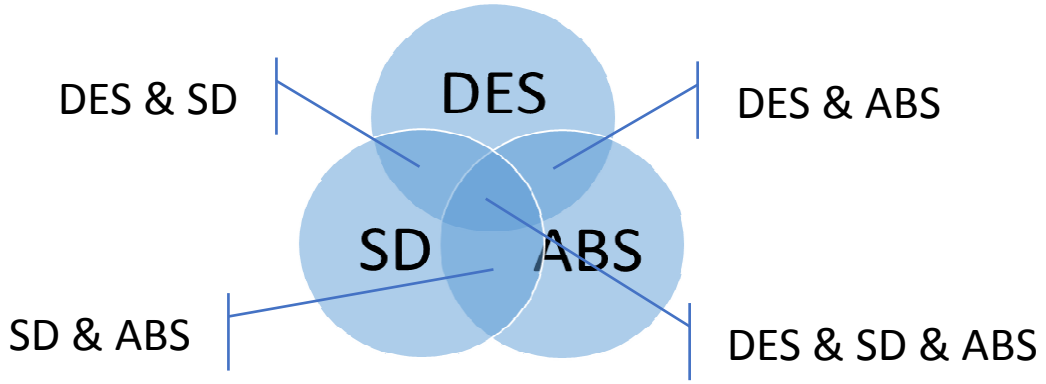

Fig. 2 - The simulation paradigms in perspective

Fortunately, some studies have already appeared which began researching the differences between the simulation modelling paradigms and how they can be used jointly to study a system from different perspectives. We feel this is a field which deserves more attention in the future.

In the next sections we present a brief description of studies that used more than one simulation paradigm to analyse the same system. These studies demonstrate the advantages of adopting a multi-paradigm simulation approach.

3.1 Comparing DES and SD

Mayo and Wichmann (2003) illustrate the of use system dynamics models to aid in strategic decision-making. The paper describes the key concepts of system dynamics and compares it to the discrete event simulation approach along a range of fundamental decisions. Some guidance on how to choose among a system dynamics or discrete-event approach is also provided.

Su et al. (2007) developed DES models to help planning for the efficient transportation of patients following a major disaster. These models proved an efficient tool for emergency planning, however they did not account for the feedback effects of human decisions which could only be accounted for by developing a SD model to supplement the DES model. This study concludes that using both modelling approaches creates a richer model and provides for better decision aid.

Morecroft and Robinson (2014) compare the usage of the SD and DES modelling approaches to model the same problem situation (a fishery); in this study the two models were developed in parallel and at each step differences in the representation and interpretation of the models were identified. They conclude that both paradigms have different modelling philosophies and characteristics and provide complementary insights, therefore SD and DES simulation should not be seen as opposing modelling approaches but rather as complementary.

Brailsford (2014) discuss if the choice of the paradigm to use is merely a question of personal preference or modeller expertise. The other assumption is, of course, that in the process of choosing the right paradigm we should take into consideration the specific features of the situation in hands, as different problems may be more adequately treated by distinct simulation paradigms. The author describes a case study in emergency care in which DES and SD were used to tackle different aspects of the same reality, pointing out some guidelines about how to choose de best simulation paradigm.

3.2 Comparing SD and ABS

Wakeland et al. (2004) present a comparative study of the application of ABS and SD modelling approaches to the study of cellular receptors. The authors conclude that the process of using two different modelling approaches was very useful because the SD approach proved to be a better tool for designing laboratory experiments but the ABS approach proved to be more suited for educational purposes. This study shows that there are advantages in choosing the best approach for the intended purpose.

Schieritz and Milling (2003) provide a comparison between the system dynamics and agent-based modelling approaches for the simulation of non-linear socio-economic systems. The authors conclude that although there are many differences between the two modelling approaches there are also similarities. The authors also identified potential integrations areas between the two approaches. This paper shows that using a multi-paradigm approach may help decision-makers develop the capacity of thinking at one and the same time of both, the forest and the trees.

3.3 Comparing DES and ABS

Dubiel and Tsimhoni (2005) studied the integration of discrete-event and agent-based simulation to simulate the movement of people in a discrete-event system. This study shows that there is value added by integrating agent-based modelling in a discrete-event simulation because the movement of people cannot be easily and accurately implemented in a discrete-event model. The use of the two modelling approaches allowed the development of a model that better mimic the real system.

3.4 Comparing DES, SD and ABS

There are not many research examples combining the three main modelling approaches and comparing them. Meyer et al. (2009) compare the three modelling paradigms (DES simulation, SD and ABS modelling) in the organizational management research. The authors conclude that each modelling paradigms has strengths and shortcomings and each one has different abilities to model the characteristics of complex systems.

Borshchev and Filippov (2004) researched how DES and SD models can be translated into ABS models. Although ABS modelling provides a rich foundation to build models of complex phenomena, the authors highlight that ABS is not a replacement for SD and DES modelling. There are applications that can be more efficiently handled with a SD or DES model. The authors also observe that when building a simulation model one should judge the advantages of using different modelling paradigms for different parts of the simulation model. In (Borshchev, 2014) the author illustrates how Anylogic may be used to study and explore the same problem with the simultaneous use of the three simulation paradigms. In this context he presents three examples (a supply-chain, an epidemic model and a product life-cycle and investment policy) in which combinations of paradigms were used to explore the same problem.

Sadsad et al. (2014), in a similar way to (Borshchev, 2014), used combinations of different simulation paradigms to tackle three distinct situations (the spread of a drug-resistant pathogen in hospitals, decision support in sexual health services and the performance of a contact centre for long-term care of senior people).

The following table try to summarize some of the most relevant contributions to the multi-paradigm simulation area:

Table 1: Comparisons of DES, SD and ABS in the literature

Authors	DES	SD	ABS	Comments
(Borshchev, 2014)	**X**	**X**	**X**	The author shows how to use a specific simulation platform (Anylogic) to mix simulation paradigms in the exploration of different problems.
(Borshchev and Filippov, 2004)	**X**	**X**	**X**	Researched how DES and SD models can be translated into ABS models; authors conclude that there are advantages in using different modelling paradigms for different parts of the simulation model.
Brailsford (2014)	**X**	**X**		Using the same case study as an opportunity to explore the two simulation paradigms, the author concludes about how to choose the most adequate.
(Dubiel and Tsimhoni, 2005)	**X**		**X**	Studied the integration of DES and ABS to simulate the movement of people in a DES system; the use of the two modelling approaches allowed the development of a model that better mimic the system.

(Mayo and Wichman, 2003)	**X**	**X**		Describes the key concepts of SD and compares it to the DES approach along a range of fundamental decisions.
(Meyer et al., 2009)	**X**	**X**	**X**	Conclude that each modelling paradigms has strengths and shortcomings and each one has different abilities to model the characteristics of complex systems.
(Morecroft and Robinson, 2014)	**X**	**X**		Conclude that both paradigms have different modelling philosophies and characteristics and provide complementary insights, therefore SD and DES should be seen as complementary.
(Sadsad et al. 2014)	**X**	**X**	**X**	Describe three case studies in which authors combine different simulation paradigms
(Schieritz and Milling, 2003)		**X**	**X**	Conclude that although there are many differences between SD and ABS there are also similarities; also identified potential integrations areas between the two approaches.
(Su et al., 2007)	**X**	**X**		Conclude that using both DES and SD modelling approaches creates a richer model and provides for better decision aid.
(Wakeland et al., 2004)		**X**	**X**	Conclude that the process of using SD and ABS was very useful because the SD approach proved to be a better tool for designing laboratory experiments but the ABS approach proved to be more suited for educational purposes.

4. Conclusions

As was mentioned before, this paper aims to complement and add new insights to a previous one which treated the same thematic (Ribeiro and Pereira, 2014). Similarly to the research work described in the examples already present in the previous paper, the new ones continue to show that there is potential in adopting a multi-paradigm approach to simulation. Some of the advantages of multi-paradigm modelling and simulation include: develop models that better capture the dynamics of the real system; provide richer analysis and insight into the dynamics of a system and cross-validation of models.

In spite of the new simulation tools in the market that support several modelling paradigms (Borshchev 2014), the practice of multi-paradigm simulation seems to be limited and made more difficult because there is a lack of guidelines for modellers and decision-makers, helping them choose which modelling paradigms should they use in each situation.

In this paper we reinforce the conclusion that, selecting the right simulation approach, or combination of approaches, for the intended purpose is challenging because modellers tend to see the world through the lens of the technique with which they are most familiar. Therefore, defining practical guidelines for the adoption of multi-paradigm simulation would prevent teams from falling in "the man with a hammer" fallacy. This is, clearly, work to do and constitutes our purpose in future efforts.

Inter-organizational Network and Organizational Strategy: A Conceptual Framework

Katarzyna Piórkowska, Wroclaw University of Economics, Wroclaw, Poland, katarzyna.piorkowska@ue.wroc.pl
Janusz Lichtarski, Wroclaw University of Economics, Wroclaw, Poland, janusz.lichtarski@ue.wroc.pl

Abstract

The aim of the paper is to identify the potential impact of node organization's participation in an inter-organizational network on the character of its strategy and consequently to develop a conceptual framework in that field addressing the potential hypotheses. The aim has been achieved through critical literature studies and initial case study research. The key findings constitute the following hypotheses to be verified in the next research stage: the more intensive network relationships, (1) the higher adjustment to the environment; (2) the weaker resources' allocation; (3) the weaker orientation to internal growth (4); the shorter time horizon; (5) the less salience of managerial goals, desires, values, attitude and behaviour.

Keywords: inter-organizational network, strategy, strategy dimensions.

Introduction

The issues of the paper emerge from the management sciences, especially strategic management in the field of an organizational strategy and a network paradigm. Most studies on inter-organizational network underline its high flexibility (Jarillo, 1988; Ma, Yao and Xi, 2009; Thorelli, 1986; Whetten, 1981) obtained through wide access to various resources (Gulati, 1999) or exchange of information amongst networked members (Burt, 1992). These factors seem to facilitate strategic adjustment and flexibility, yet some uncertainties remain unexplained, as most researchers focus on flexibility of a network as a whole, and they pay much less attention to the internal strategic flexibility of node organizations.

The aim of the paper is to identify the impact of an inter-organizational network on the character of node organization's strategy and to develop a conceptual framework in that field. The main research question is: does and how the intensity of network relationships influence dimensions of organizational strategy? The aim has been achieved through critical literature studies and case study research.

Insights into the Inter-Organizational Networks Literature

Inter-organizational networks (IONs) constitute a developing research area in management science. The various research on identifying, describing, and explaining the mechanisms of creating and functioning IONs has been conducted (e.g. Borgatti and Foster, 2003; Castells, 2010; Dagninio and Rocco, 2009; Delporte-Vermeirena *et al*., 2004; Emirbayer, 1997; Gibbons, 2004; Granovetter, 1973; Harrigan and Newman, 1990; McFadyen *et al.*, 2009; McPherson *et al.*, 2001; Powell, 1990). Yet, although most of the scholars are focused on the inter-organizational network as a whole: e.g. the essence and types of inter-organizational networks (Boulanger, 1995; Child and Faulkner, 1998; Granovetter, 1973), the components of networks (Bianchi and Bellini, 1991; Prahalad and Ramaswamy, 2000; Thorelli, 1986), principles of managing networks (Järvensivu and Mőller, 2009), innovative processes and knowledge management (Dent, 2002; Grant, 1996; Harari, 2002) and so forth, they do not concern the problem of

the impact of the participation in an inter-organizational network on the character of traditional components of an organization like organizational strategy what constitutes a research gap in that field.

Organisational Strategy and Its Dimensions – Theoretical Background

The strategy of an organization is undoubtedly a multi-faceted and multidimensional phenomenon determined by ontological-epistemological variation in that realm what results in ambiguity of perceiving strategy's important dimensions. Admittedly, it ought to be emphasized that multidimensionality of strategy limits the dominance of one or more dimensions so as to succeed, however, literature studies resulted in selecting the most frequently explored and explained.

First, one of strategy dimensions highlighted by the scholars is organization's alignment with its environment (e.g. Miles *et al*., 1978; Mintzberg, 1978; Pearce and Robinson, 2000) - the salience of adjusting to the environment in enterprises' strategic behaviour. Similarly, according to Andrews *et al*. (2009), strategy content means how an organization interacts with its environment and how it seeks to improve its performance. Secondly, one can find managing major internal interdependencies as an important strategy dimension (e.g. Miles *et al*., 1978; Mintzberg, 1978) – understood as the salience of internal (organizational) resources. Thirdly, some scholars (e.g. Miles and Snow, 2003; Mintzberg, 1978; Quinn, 1980) emphasise a strategic change and the speed of changing over time - attitude towards strategic changes and a change as the whole as well as the degree of flexibility in reacting to environment signals. Moreover, importance of managerial desires and plans including also managerial attitudes and behaviour are taken into consideration (e.g. Beer and Davis, 1976; Mintzberg, 1978). When it comes to the salience of the degree to which an enterprise focuses on internal growth, some scholars emphasize the instance of an orientation towards product-market development (e.g. Miles *et al.*, 1978). Additionally, what is strongly stressed regarding the dimension of a strategy, time horizon, even profitability time horizon is critical with regard to the time horizon of particular goals and plans to be attained or the time allotted to make profits (e.g. Chandler, 1962; Pearce and Robinson, 2000). The next criterion taken into account in analysing strategy dimensions is the degree of incrementalism what results in either deliberate strategies or incremental ones (e.g. Mintzberg, 1978). Value creation constitutes the next strategy characteristic in terms of realizing short-term interests of enterprise's shareholders *versus* best long-term value of the enterprise (e.g. Frery, 2006, Krause, 2012). The role of imitation extent *versus* innovativeness one is also highlighted in literature studies describing strategies mainly in terms of the degree to which an organization is focused on making processes innovative or imitated (e.g. Frery, 2006; Grant, 2010). Furthermore, resources allocation issues perceived as crucial due to strategy features like a perimeter tend to be one of very important hallmarks of a strategy understood as the allocation of own or foreign resources as well as deliberate resources' allocation *versus* resources emerging from day-to-day activities (e.g. Frery, 2006; Grant, 2010; Pearce and Robinson, 2000).

Synthetizing strategy dimensions having been presented, the following aggregated dimensions will be taken into account: (a) adjustment to the environment and flexibility in reacting to environmental stimuli, (b) resources' allocation (salience of internal resources); (c) orientation to internal growth, (d) time horizon, (e) salience of managerial goals, attitudes and behaviour.

Inter-Organizational Network and Strategy Dimensions' Intensity – The Research Framework

The research model encompasses an independent variable, dependent variables, moderator and mediator ones. An independent variable constitutes the intensity of network relationships. The strategy dimensions having been aforementioned will be considered as dependent variables. All of the mentioned variables may vary in their extent from low to high.

Consequently, as a result of analysing and synthetizing strategy dimensions in terms of inter-organizational network participation, the initial research framework includes the following hypotheses:

H1: The more intensive network relationships, the higher adjustment to the environment and the higher flexibility in reacting to environmental stimuli, and consequently the more emergent organizational strategy.

H2: The more intensive network relationships, the weaker resources' allocation (more focus on foreign resources).

H3. The more intensive network relationships, the weaker orientation to internal growth (more focus on adaptation and less focus on proactivity).

H4. The more intensive network relationships, the shorter time horizon.

H5. The more intensive network relationships, the less impact of managerial goals, desires, values, attitude, behaviour on organizational strategy character (the higher managerial adaptation).

Additionally, so as to complete the research framework, the moderator variables: network size, centralization level, coherence level, type of dominant relationships, relationship's time of lasting as well as mediator variables**:** management staff characteristics (e.g. personality traits, attitudes/behaviour) have been recognized.

Single case studies performed by the authors show that the influence of inter-organizational network is not obvious. While entering the network, the strategies of some node organizations became more flexible and open, based on external resources, and with shortening time horizon. Those changes are coherent with theoretical considerations. On the other hand, one can observe many instances of organizations which strategies became more narrowed and closed (focused only on the network), more formalised, reactive and rigid (longer time horizon), etc., as the "new" network environment is perceived as more stable and predictable.

Concluding, participating in an inter-organizational network undoubtedly influences the character of an organization's strategy, yet the direction of the influence needs to be verified. It seems that selected dimensions predispose to describe the organization's strategy in an inter-organizational network as variables determined by the character of network relationships intensity.

Conclusion

The paper introduces a framework regarding strategic adjustment to network environment. Synthesizing diverse theoretical traditions that influenced studies on inter-organizational networks, it might be envisaged that the paper offers new insights into established literature, especially it shows a quite different perspective – an organizational strategy triggered rigidly by network relationship intensity.

The future research directions depend significantly on the quality of strategy dimensions' measures, which have not yet been critically evaluated. The purpose of the next research steps is to develop, review, and evaluate the adequacy of the measures employed to capture strategy dimensions' constructs and to complement recent discussions of strategy operationalization (Ginsberg, 1984; Snow and Hambrick, 1980; Venkatraman and Grant, 1986;) and use these measures in *large-n* questionnaire studies. As well as this, the conceptualization highlights some new research areas to be explored, e.g. how a network influences other elements of the whole management system. Single studies of node organizations suggest

that contemporarily network context may be one of the most influential factors in designing and developing organizations.

Multi-Agent Decision Support System for Evaluating Impact of Intelligent Systems in the Process of Managerial Decision

Cornelia Novac Ududec[1], Liliana Mihaela Moga[1]
[1]Dunarea de Jos University of Galati, 47 Domneasca Street, 800 008 Galati, Romania
E-mails: cornelia.novac@ugal.ro, liliana.moga@gmail.com

Abstract

The paper presents the results of designing and implementing a prototype multi-agent system aimed to evaluate the impact of using intelligent systems for decision-making. In order to develop the decision support system it has been used the 'Modelling-Based Agent' paradigm through which it has been achieved an approach adequate to the intended purpose. The paper shows the model, components and functions of the system.

Keywords: management, decision, multi-agent system, decision support system

Introduction

This paper presents a prototype of multi-agent system that performs impact evaluation of using a Decision Support System (DSS) in making decisions by human decision makers. Research carried out by Williams et al (2007) and Lilien et al (2004) have proven that the use of a DSS system does not always improve the decision quality, but it can help users to understand and better solve a decision problem. Kohli and Devaraj (2004) remarked that the use of a DSS throughout an extended period leads to the improvement of decisions as system outputs. Therefore, it is very important to be understood the way a DSS helps the user to make the best decision.

The research performed so far have not given due consideration to the effect had by expertise in using a DSS in the strategy of decision making and quality of results. Most experiments have tested once a DSS by making preliminary tests on a group of subjects and comparing the results with another benchmark group, which did not use a DSS in decision making. Lack of long-term studies concerning the results of using DSS was imputed to the high cost of investigations. Because of ignoring the system survey, the research results construction can be made from two perspectives: by taking into account the lack of subjects' expertise or, second, a large difference among the subjects' levels of expertise.

1. Prototype Model of the Multi-Agent Decision System

An agent-based economy is a relatively new area that deals exclusively with the study of using agents in solving various kinds of economic problems from a particular field. The purpose of agent-based economy derives from A-Life and consists in creating artificial economies by means of economic interactions among agents who initially have no knowledge about the environment, but have the ability to learn. Then is continued with observing the types of markets, institutions, and technologies, which develop agencies, the way in which they coordinate their actions and how they organize themselves in an economy.

An intelligent decision system can be defined as a system that uses the combination of models, analytical techniques and information retrieved, in order to help develop and evaluate the most adequate alternatives (Sojda, 2002). These systems are focused on strategic decisions and not on operational decisions. More precise, the DSS contributes to

the decrease of uncertainty faced by managers when they need to make decisions regarding future options.

The distributed decision is adequate for solving problems where the complexity is an obstacle to existing only one concept maker for decision elaboration, on the one hand, and on the other hand, to be able to manage the entire problem. Intelligent Decision Systems reduce the time during which decisions are elaborated in the real context, and improve the decisions quality and consistency. The problem raised by their use is that it is based all the time information, experience and knowledge about the process.

The intelligent multi-agent decision support system has been developed using the MBA (Modelling-Based-on-Agents) paradigm and is based on production rule judgment. The system was designed using Jadex platform with the Prometheus methodology. Details about this technology and about how it was used and adapted are presented in the paper.

Used System of Production Rules

A system of production rules (SPR) has as method to represent knowledge the propositional logic and logic of first order predicate, in a declarative and unambiguous manner. The SPR uses an inferential engine for processing rules, replacing in conditions (premises) data and facts to infer conclusions whose results are actions. A first order production rule for knowledge representation has the structure from relation (1). They are stored in the knowledge base of the system and are then subjected to a filtering process.

IF <condition> THEN <action> (1)

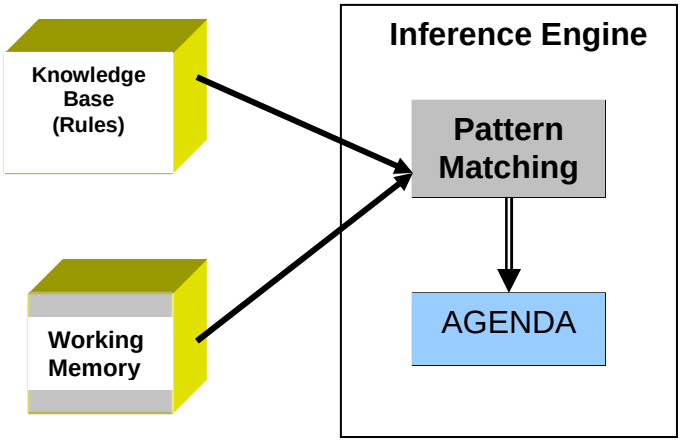

Fig.1. The System Model Rules Production Based

Filtering or pattern matching is the process of extracting some facts existing or new from rules. Inference engines use various algorithms for pattern matching, such as: linear algorithm, Rete, Treat and Leaps. Figure 1 shows the high level of rules processing (filtering).

In the developed system it has been used a Drools engine. Drools is an engine for rules processing which has implemented the forward chaining reasoning based on a strengthened Rete algorithm and which is adapted for the Java language. The processing engine is made up of two main parts: Authoring and Runtime. In the Authoring process, rules are saved in a DRL or XML file, which are entered into a compiler that checks grammatical correctness

and generates an intermediate structure. This structure is then passed to a Package Builder that carries out packaging, shown in Figure 2.

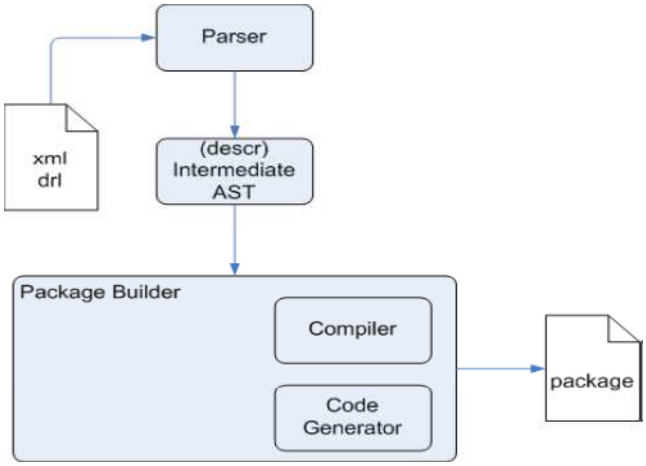

Fig. 2. Authoring components (extracted from Jadex Tutorial)

In the Runtime process several components are involved, as seen also in Figure 3. A base of rules (RuleBase) is a component that contains several packages. These can be added or deleted to/from the base at any time. One or more rules can be instantiated in the working memory (Working Memories). The working memory consists of a number of components that include Working Memory Event Support, Truth Maintenance System, Agenda and Agenda Event Support. Inserting an object can result in the creation of one or more activations and it is the Agenda that has the responsibility for planning their execution.

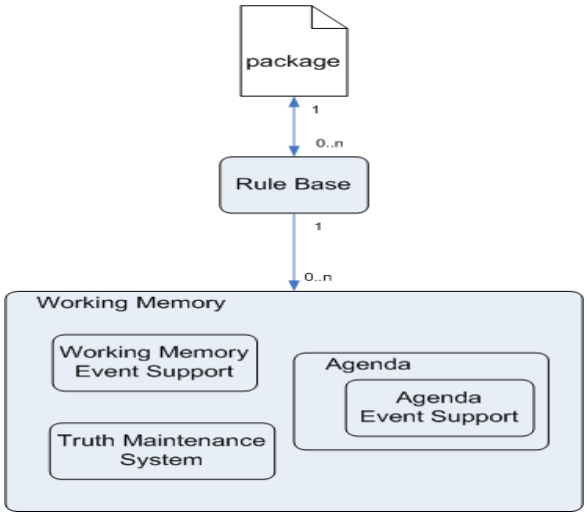

Fig. 3. Runtime components (extracted from Drools Tutorials)

The Inference Engine

The Agenda has Rete characteristics. During Working Memory Action rules can be selected and eligible for execution. One single Memory Working action may result in rules that are more eligible. When a rule is selected, it is created and placed activation in the Agenda. The

Agenda controls the execution order of these activations using a strategy of conflict solving. The inferential engine operates in a two-step recursive manner as can be seen from Figure 4.

1. Working Memory Actions. An action working with the memory takes place most of the working time being a Consequence or a Java main application. As soon as a Consequence has been finished or when the Java main application calls FireAllRules method, the engine switches to the Agenda Evaluation phase.
2. Agenda Evaluation. The Agenda tries to select a rule to execute. If finding the rule, executes it, and unless finds no rule from the existing ones, gets back to Working Memory Actions, and the process recurs until the Agenda becomes empty.
3. The recursive process ends when the Agenda is empty, in which case the control comes to the caller application. During Working Memory actions, no rule is activated.

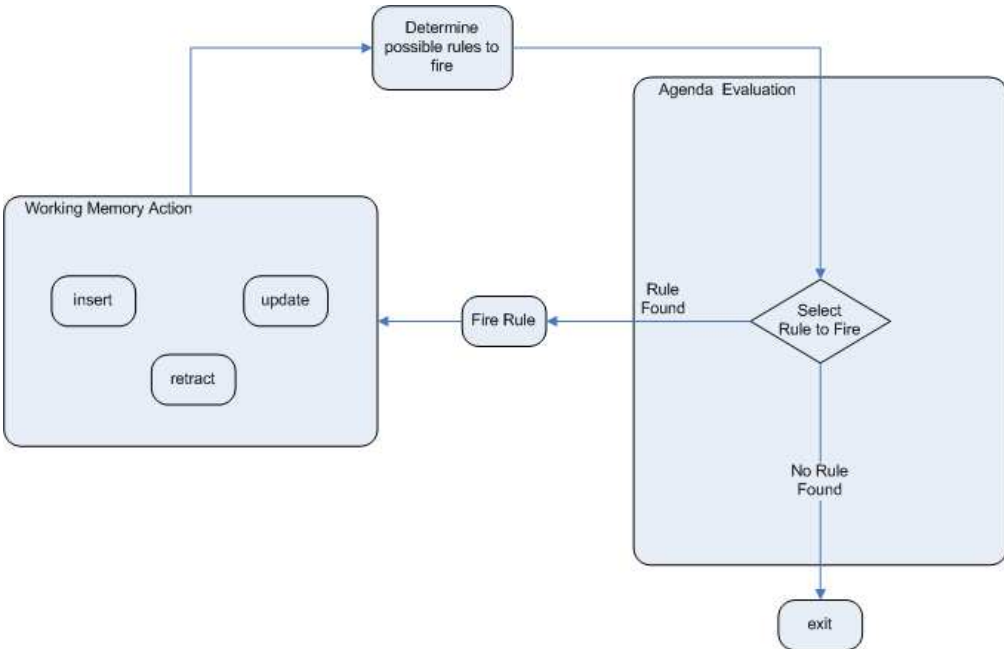

Fig. 4. Execution phases of the inferential engine (extracted from Dools Tutorials)

Maintenance of the consistency (truth value): Let us consider a set of facts. The inferential engine applies facts to the adequate rules and changes them where necessary. If the new facts determine other rules to enter into competition, then they are applied. Eventually, all necessary rules are enabled and facts are stored in the working memory, representing the "true" truth value or at least "true" as it is understood by rules.

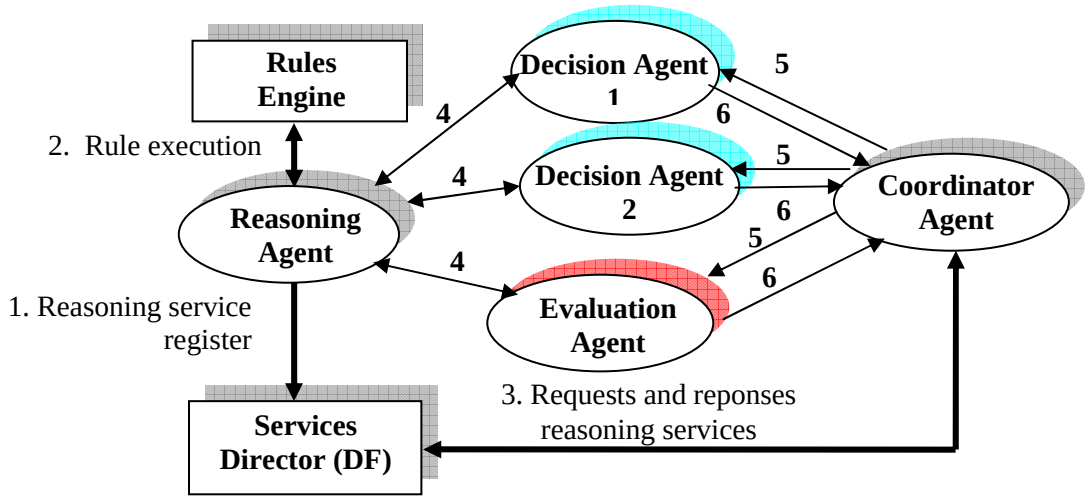
Conflicts solving: When there are one or more actions in the agenda, they are in conflict, which involves the use of conflict solving strategy with the purpose of determining the order of execution. The default strategy for conflict solving in Drools is Priority and LIFO (Last In, First Out). By I, the user can specify which rules have higher priority than others. Therefore, the rule with the highest priority will always be preferred. The LIFO priorities imply that there may be rules that have the same priority and in this case they will be executed according to the queue principle, that is, "first come, first served".

2. Designing and developing intelligent multi-agent decision support system

The purpose of this step is to develop a framework to support the decision making process within the real economic environment using artificial intelligence techniques of the Multi-Agent Systems type and Rule-Based Reasoning.

The software instrument designed and developed enable to simulate scenarios for evaluating the consequences of the decision-making processes. Designing the prototype for the case study has been carried out using the Prometheus methodology (Padgham and Winikoff, 2004) and, respectively, JADEX agents platform (Braubach and Lamersdorf, 2004), which we enlarged it as we will hereinafter specify.

Agent architecture implemented: The multi-agent system prototype is made up of five agents: two agents for one type of decision problem, a coordinating agent and an agent for performance evaluating the decision process and subjects and a reasoning agent (Figure 5).



Legend:
4 – The agent requests reasoning and receives the conclusion
5 – The coordinating agent addresses an expertise application to a certain agent
6 – The called agent returns conclusions to the caller agent.

Fig. 5. System agent architecture (extracted from Novac Ududec, 2015)

Integrating the Drools environment with the Jadex agent environment

The purpose of developing the new system was to extend the Jadex agent platform through adding a rule-based inference mechanism. The Rete-Drools engine of rules has been integrated into a reasoning agent that is capable to execute deductions. In this way, it has been taken the entire BDI functionality of the Jadex platform, including the purpose-guided reasoning and fact-guided reasoning. In addition, it has been achieved a simultaneous mechanism of inference incorporated into agents based on rules.
Knowledge is represented by rules and facts. The rules are specified in a file, and the facts in JavaBeans. The rule engine can create, delete and manipulate objects (facts). The facts are created using builder classes that employ inheritance mechanisms for each field so the engine can access the object. The facts have been entered in the working memory from

Drools and the engine can use these facts assigned in order to evaluate and map the conditions.

The rules are represented in a DRL or XML file. A DRL file is an ordinary text file which can have several rules. The rules are written by using the first-order logic and can be conjunctive rules.

A rule has a part of condition and one of consequence or action. In Drools, the first part is called Left Hand Side (LHS), and the second, Right Hand Side (RHS). In this way, both components from the definition of the „IF-THEN" rule become „WHEN-THEN":

```
rule <name>
attributes
when
        LHS <conditions>
then
        RHS <actions>
end
```

A rule should have a unique name in the package. The attributes are optional and influence the rule behaviour. LHS can have zero or more conditions. If empty, the condition is evaluated to "true". RHS must contain a list of actions that will be executed (for example: inserting, deleting, updating facts).

Reasoning Agent

The reasoning agent ensures the connection among agents and the Drools engine. It is described in Figure 6. The agent creates a service defined in the Directory of Jadex Reasoning Service (Directory Facilitator - DF), offering its service of reasoning.
The rule base and PackageBuilder are stored in the base of beliefs for creating a rule when the reasoning agent is created. These are shown as follows:

```
<belief name= "builder" class="PackageBuilder">
<fact>new PackageBuilder()</fact>
</belief>
<belief name= "rb" class="RuleBase">
<fact>RuleBaseFactory.newRuleBase()</fact>
</belief>
```

The agent has to declare a Jadex plan where will take place all communications with the Drools engine. This plan is executed when the agent receives a reasoning request via the FIPA protocol. When the facts will be assigned in the Working Memory, the filtration process occurs and the the rules will be activated and will start the execution. When finishing deduction, the control is rendered to the application and conclusions are sent back to the coordinating agent.

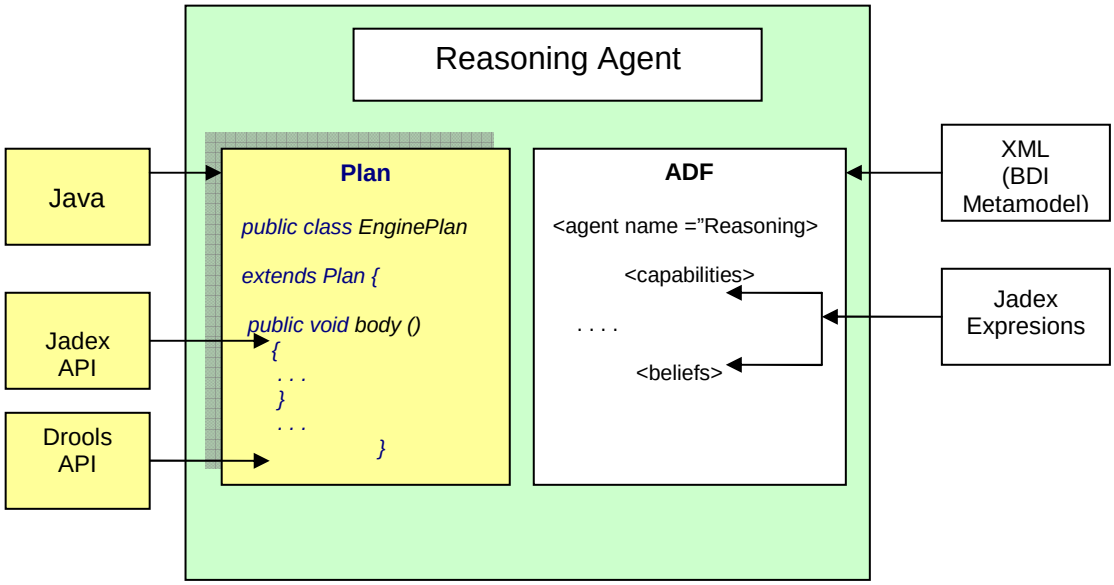


Fig. 6. Reasoning Agent

Coordinating Agent

It is the agent of interface with the user from which it takes over the consultation request of the system which then directs it to the agent of decision corresponding to the request. This agent will receive the consultation results from the decision agents and will transmit them to the evaluation agent, from which will then receive the outcome of evaluation and will make it known to the user. In addition, this agent will receive the results of solving problems by the subjects before employing the system and will transmit them to the evaluation agent.

Decision Agents

The decision agents can be virtually howsoever, one for each decision problem that is intended to be solved. They have their own base of rules. In the case of the presented system, two agents have been designed.
The Decision Agent 1 solves the decision problem of an individual who would want to place an amount of money in deposits or savings depending on certain conditions.
The Decision Agent 2 solves a decision problem of a customer who wants to place a sum of money in various investments. The agent checks the various aspects of individuals' financial image compared to normal environments and provides several opportunities.

Evaluation Agent

This agent, as we have already shown, receives from the coordinator agent the evaluation request together with the results obtained by the decision agents and subjects individually, executes the evaluation and communicates result to the coordinator agent. This agent also has its own base of rules.

Communication and Interaction among Agents

In JADEX, the communication between two or more agents is performed through message-events. Normally these message-sentences appear in the conversation among several agents. The conversation handling mechanism is based on the FIPA message structure in which are used three parameters: conversation-id, in-reply-to, reply-with. The conversation-id parameter has a unique value and groups together more messages belonging to the same conversation. The in-reply-to parameter identifies a message that is a response of a previous message corresponding to the reply-with parameter. The management process of these conversations may be predisposed to errors if managed by the programmer by means of the flowcharts interaction of the messages. Therefore, as an alternative, Jadex provides the possibilities of the Interaction Protocols that implement the FIPA interaction standards. These allows that the agents participating in a conversation be programmed by using abstract request. In the proposed system it has been used Interactions Protocols Jadex.

Conclusions

The decision support systems can restrict the decision making process in three ways: by limiting the available features, restricting the order of operations and by limiting the user control over parameters. The multi-agent system designed and implemented called SISD has proven its usefulness, proving the three working assumptions concerning the impact of using a DSS in decision making. Novac Ududec (2015) presented the results of testing the designed system. The assumptions tested were decision effectiveness, efficiency and quality. The first two assumptions were proven, not the third, in the sense that experience in problem solving leads to a better performance in making decision, but the expertise of a DSS does not have a significant impact.

The DSS users increase their effort investment throughout the working sessions until reaching a certain threshold. This is consonant with the cost-benefit principle that postulates that the major objective of decision makers is both increasing the decision accuracy or quality and reducing the effort.

Abstract

This paper aims to present a conceptual model on the efficiency of waqf that are responsible in collecting, managing and distributing waqf in Malaysia. Waqf is an Islamic religious collected on the rich and well-to-do members of the community for distribution to the poor and the needy as well as other beneficiaries based on certain established criteria according to the Qur'an. The main aim of waqf is to protect the socio-economic welfare of the poor and the needy.The paper reviews and synthesises the relevant literature on waqf as tool of economy growth for Muslim and its efficiency. The paper then developed and proposed a conceptual model to study the efficiency waqf institutions.The paper identifies the appropriate methods to evaluate efficiency waqf institutions. Such evaluations are crucial for the Islamic financial system to function effectively in order to achieve the noble objectives of socioeconomic justice through proper distribution of wealth.This paper presents a conceptual model of efficiency of waqf institutions which would be useful for further empirical research in this area. The findings are not only relevant and applicable to Malaysia but also to other Muslim countries.

Keywords: Waqf, lslamic Wealth, Justice, Distribution

1. INTRODUCTION

Waqf is an act of retaining something for the benefit of others. Kahf (1998) clearly defined it as holding and preventing of a Maal (an asset) for the purpose of using the benefits in meeting its objectives of philanthropy. According to fiqh scholars, waqf is to preserve and hold certain properties solely to provide for certain effort of improving the mankind wellbeing and any utilization of it outside of its main objectives are prevented (Zahrah, 2007).

The terminology of *waqf* originates from an Arabic word, which carries the meaning of restrain (*al-habs*) and restrict (*al-man'*).In detail, *waqf* is defined as a form of direct (*sarih*) or indirect (*kinayah*) property dedication in which the property is restrained and its benefit is only applicable for general or specific charitable purposes. This means, the rights of the *waqf* founder towards the property is restrained from any kind of business transaction, inheritance, gift (*hibah*) or will. Any type of income, revenue or profit gained from the property under *waqf* must also be spent for the general or specific welfare with the intention of the founder to be closer to Allah SWT. Therefore, the property no longer belongs to the owner, is unreturnable to the former owner and is not able to be possessed by anybody. Generally, *waqf* is classified into two – *waqf khayri* and *waqf ahli*. *Waqf khayri* refers to the *waqf* in which its benefit is dedicated for the use of all groups of society. The purpose of this *waqf* is general (*waqf 'am*). While *waqf ahli* refers to the *waqf* that is set for a specific purpose or group. The purpose

of this *waqf* and the target group of receivers are fixed from the beginning, whether it is for family members or a special group of people (*waqf khas*). Whereas *waqf musytarak* is a combination between these two forms of *waqf*. Part of the *waqf* property is dedicated to family members and another part for the use of the public.

Waqf is defined literally as hold, confinement and prohibition. Technically, it is a sadaqah mechanism that is continuous in nature. Waqf assets must be used within a certain domain of usage according to the specification made by one who contributes the waqf. It cannot be disposed of outside of such purpose (Kahf, 2003; Abul Hassan and Shahid, 2010). Thus, it is understood that any property subject to waqf must not be perishable and they are meant to give constant benefits to the society.

Generally, waqf is divided into two kinds which are waqf 'amm (general) and waqf khas (specific). It can also be classified as public and private respectively as pointed out by Hassan (2010). The former refers to the dedication in waqf assets for the benefits of the society at large while the latter refers to the dedication of waqf assets for designated purposes or for the benefits to be enjoyed by certain beneficiaries named by the person who gives waqf.

Sabit and Hamid (2006) illustrated the attributes of waqf, which are irrevocability, perpetuity and inalienability. These characteristics indicate that the assets should be held for a long-time purpose and once it is declared as waqf assets, it cannot be revoked. It will belong to the society and usually, a third party will be appointed as the manager who will undertake the responsibility to manage and oversee the waqf assets. Interestingly, these characteristics require a higher degree of management so as to ensure the waqf assets could sustain for a longer period of time or it could be perpetual and assure that the benefits would withstand.

According to Mazrul Shahir (2012) waqf institutions play a pivotal role in enhancing social welfare. He asserts that the management for waqf institutions need to be improved and equipped with modern approaches in order to ensure better and efficient services are provided to the community. It is understood that public services for Muslims can be provided through waqf system. Waqf is seen as the medium for equal distribution and reduces inequity in the society.

The word waqf is an Arabic word which literally means to stop, to hold, confinement or prohibition (Kahf, 2007b, p. 2). It is a singular form, in which the plural form is *awqaf*. In Islamic law literature, waqf denotes holding certain property and preserving it for the exclusive benefit of certain philanthropy and prohibiting any use or disposition of it outside its specific objective (Kahf, 2007b). Kahf further adds that waqf is an endowment of money or property made for benevolent reasons.

Meanwhile Gaudiosi (1988, p. 1234) states that waqf is "the detention of the corpus from the ownership of any person and the gift of its income or usufruct, either presently or in future, to some charitable purpose". She adds that, while "ownership of the waqf property was thereby relinquished by the founder, it was not acquired by any other person; rather it was 'arrested' or 'detained'".

The word waqf has since been widely used not just by Arabs, but also by Muslims from other parts of the world. This has resulted in different transliterations, such as *wakf, vakf, vakif, vaqf, wakaf* (Islahi, 2003, p. iii). Waqf is also known with different names, such as *habs* in North and South Africa (Kahf, 2007b) and *qadsh* in Hebrew (Gil, 1998, p. 126).

In brief, waqf is a donated property used for the benefit specified by the donor, in which the purpose must be benevolent, normally serving community interests(McChesney, 1991, p. 10). The donor can state his/her intention to do waqf verbally or in writing (waqf deed), although the current practice requires the undertaking to be in writing.

2. ECONOMIES OF WAQF

The question that we may ask is why we classify waqf as economic matters. Let we look it from the basic premise, that is the definition. This definition could be divided into two, language and scholar perspectives. From language perspective, as discussed in Ariff (1991), waqf is spelled out as *Wakfun* and formally known as *Wakf-alal-aulad* or religious endowment. Alternatively, it is typically denoted as a building or plot of land8devoted for religious or charitable purposes.

Scholar such as Imam Abu Hanifah said that waqf means the detention of specific thing in the ownership of waqif and the devoting of its profit, products or other good objects for the poor. Imam Abu Yusuf and Imam Muhammad said that waqf signifies the extinction of the waqf`s ownership in the thing dedicated and detention of all the thing in the implied ownership of God. It shows that its profits may revert to or be applied "for the benefit of mankind". Another scholar, i.e., Kahf (1998), he defines waqf as "holding a *Maal* (property) and preventing its consumption for the purpose of repeatedly extracting its usufruct for the benefit of an objective representing righteousness or philanthropy."

Hence, waqfis very much closed to economic in different aspects: (i) it gives the transfer of *ownership* of the said property to a trustee; (ii) the said property is taken from the owner's wealth such as cash waqf, it reduces the consumption of owner but it create a "transitory" wealth of recipient or it generates benefits of other generation via intra or intergenerational transfer; and (iii) perpetuity concept of waqf remains as long as its asset lasts, hence the accumulation of stocks (or investment) remain with the trustee; and (iv) finally it increases the sources of revenue and expenditure of the trustee.

3. EFFICIENCY WAQF FRAMEWORK

The convenience of assessing the multiple input and output variables of these entities by not requiring congruity and an apriori relationship makes it a very popular management tool in many application areas (Akçay, Ertek, & Büyüközkan, 2012). According to the authors, DEA is a widely used benchmarking tool to evaluate performances and efficiency.

Several papers discussed this in relation to banking or financial institutions' efficiency (Berger, Leusner, & Mingo, 1997; Berger & Mester, 1997; Drake, Hall, & Simper, 2009; Halkos & Salamouris, 2004; Holod & Lewis, 2011). Since there is no publication as yet that discusses the use of DEA in measuring Waqf institutions' efficiency, the measurement of efficiency used for Islamic banks and Zakat department will be referred to as the identified proxy method in measuring the efficiency of Waqf institutions.

Sufian (2009), conducted a study to find the determinants of banking efficiency during Asian financial crisis in 1997 from the Malaysian perspective. The study investigated Malaysian banking efficiency during the crisis using the DEA approach. In his research, Sufian (2010) presented an analysis that employed DEA method on quarterly data to construct the efficiency frontiers. Nor Hayati Ahmad, Mohamad Akbar Noor Mohamad Noor, and Fadzlan Sufian (2010) further provided an empirical study that measured Islamic banks' efficiency throughout all the Muslim countries that were practicing Islamic banking during period of 2003 to 2009. This vast research was dominated with macroeconomic findings that revealed the countries' banking characteristics and economic indicators which were linked with the Islamic banking sector's performance.

Norazlina Abd and Abdul Rahim Abdul (2011) in their paper discussed the efficiency measurement on Zakah Collectors Board in Malaysia. The study examined the determinants of Zakah collection in Zakah institutions and then measured the efficiency of the organization using technical efficiency (TE), pure technical efficiency (PTE) and scale efficiency (SE).

In DEA, Berber, Brockett, Cooper, Golden, and Parker (2011) analyzed the efficiency of SPEs (Social Profit Enterprises) and described social profit as "the amount of social and humanitarian benefit gained as a result of investing in the well-being of others". DEA provided estimates of potential improvements for inefficient DMUs. The study indicated that in not-for-profit (NFP) organisations where market prices or relative values of outputs are not readily available, DEA emerged as a particularly useful service management technique.

Berber et al. (2011) divided the analysis into two stages i.e. Stage 1 for fundraising efficiency and Stage 2 for service provision efficiency. In the study, both stages were considered as two-stage linked DEA analysis for NFP organisations. NFP organisations were noted as different from the private finance sector or banking sector in the above literatures, yet their motive of operation was clearly different. Nevertheless, these findings in finance sector can still be utilized as proxies in this analysis. For example, banking sector uses identical input information which is the number of its staff.

Literally, two-stage DEA has been discussed in Halkos, Tzeremes, and Kourtzidis (2014) as an imperative model for decision maker of a supply chain, a network processes within peer DMUs (Cook & Seiford, 2009), innovative of two parallel sub-processes from a two-stage process (Yu, Shi, & Song, 2013), fuzzy multi-objective stages approach (W.-K. Wang, Lu, & Liu, 2014) and functioning to manage undesirable input-output of two-phase model (Huang & Li, 2013). The idea was pioneered by Seiford and Zhu (1998) and enhanced in detail by Y.-M. Wang and Chin (2010).

The existing multi-stage DEA models can be categorized into two; closed-system and open-system models. In this study we choose an open-system where the second stage input not necessarily from the first stage output.

Table 1 : Waqf Framework 1st Stage : Waqf Collection

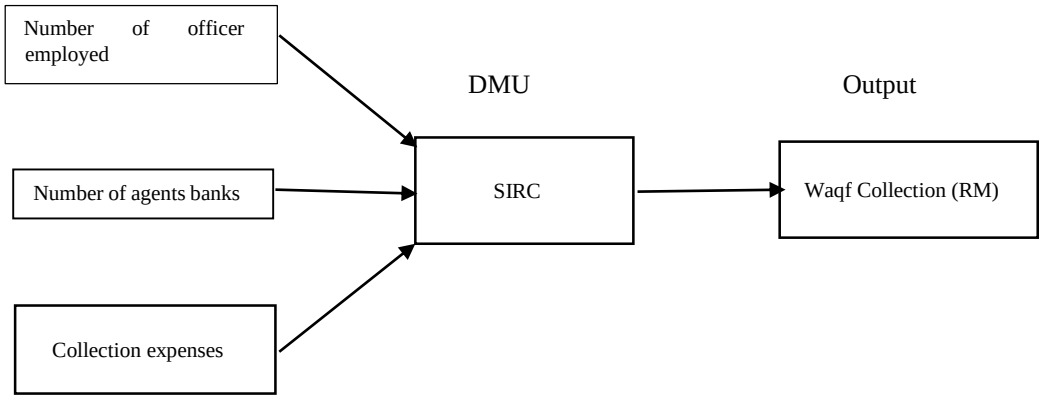

Table 2 : Waqf Framework 2nd Stage

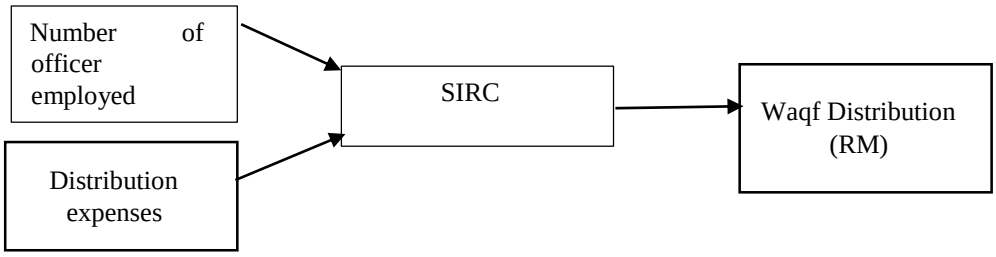

Henceforth in this study, DMU is to represent SIRCs in Malaysia from thirteen states altogether. SIRCs are managed by the state government and Waqf funds are run by each SIRC according to the states' SIRC policies. As in this conceptual analysis of Waqf SIRCs in Malaysia, panel data analysis of its efficiency will consider all the internal information within the institutions to measure the score of efficiency. The analysis will measure TE, PTE and SE of Waqf SIRCs in both constant return to scale (CRS) and variable return to scale (VRS) scenarios.

The data analysis panel would consist both collection and distribution information from the thirteen states' SIRCs in Malaysia by measuring two-stage DEA analysis. The input information for Waqf collection (WC) efficiency will be the number of officer employed, number of agent banks and the collection expenses. The output will be the Waqf collection in the value of currency. From these figures, the efficiency of Waqf collection can be generated.

The analysis will be continued to the second stage which is to measure the Waqf distribution (WD) efficiency by the input information of the number of officer employed (for distribution) and distribution expenses. The output information will be the Waqf distribution in the currency value. Then the distribution of Waqf efficiency score will be measured.

4. CONCLUSION

From this conceptual modelling of the public Waqf efficiency measurement with DEA, efficiency scores according to the specific DMUs studied can be generated. TE measurement would be an accurate indicator to the best management practice of each and every SIRC studied. From the scores obtained in DEA, it would be possible to establish the range of efficiency scores from zero value which equals to zero per cent efficiency to the value of one which equals to a hundred per cent efficiency score. The scores can also establish a benchmark, particularly for the most efficient DMU (SIRCs) to act as the role model for other DMUs in order to evaluate their performances.

Measuring both stages of collection and distribution of Waqf will provide detailed analysis of its operation. Efficiency refers to how well the institutions are using its resources (e.g. the staff, expenditure, etc.) to meet its objectives of socio-economic justice (e.g. long-term objective of reducing poverty)

Impact des CDS sur le cout de la dette publique : cas de la zone Euro

Souhir Amri Amamou, Doctorante chercheur en science économique et gestion, Laboratoire Bestmod, Tunisie, e-mail :amri_souhir11@yahoo.fr

Sleheddine Hellara, Professeur en science économique et gestion à l'Institut Supérieur de Gestion de Tunis, Tunisie, e-mail :slaheddine.hellara@isg.rnu.tn

Abstract

Les CDS sont des produits diversifiés très récents sur les marchés mondiaux dont l'analyse a suscité l'intérêt des chercheurs depuis leur apparition et s'est amplifié suite à la crise des subprimes en 2008. Ces produits, dont la commercialisation était vraiment rapide et facile, sont devenus l'un des plus importants marchés des dérivés de crédit mais aussi l'un des plus critiqués.

L'objet de ce travail est de répondre à la question : **Quel est Impact des CDS sur le cout de la dette publique : cas de la zone Euro ?**

Afin de répondre à cette question, nous chercherons à détecter le rôle joué par ces produits en situation de crise via l'analyse de la revue de la littérature et nous vérifierons nos résultats théoriques par une démarche empirique portant sur le marché de la dette souveraine dans le cadre de la crise de la zone Euro

Mots clés : CDS, dette obligataire publique, crise souveraine

Introduction :

L'accroissement des risques menaçants le système financier à inciter l'émergence de plusieurs produits de couverture. Ce travail se focalise sur l'un de ces produits à savoir le marché des swaps sur défaillance de crédit(CDS).C'est un contrat par lequel un vendeur de protection s'engage en contrepartie d'une prime appelée spread de CDS de dédommager l'acheteur en cas d'événement affectant la solvabilité d'une entité de référence.

Les CDS peuvent être un moyen d'alarme contre toute perturbation touchant la dette. D'ailleurs, selon Ismailescu et Kazemi (2010), dans un cadre d'étude menée sur les conditions des marchés émergents, l'utilisation des primes de CDS aide les participants au marché d'obtenir des estimations des changements défavorables de la qualité de crédit. Donc, les CDS peuvent présenter à la fois un moyen d'influence et de réflexion des conditions du marché de la dette.

Cependant, la détermination du signe et de la nature de la relation existante entre les deux marchés reste une tache assez complexe. Certains considèrent que les CDS favorisent la confiance dans tout le système financier ainsi, ils favorisent la stabilité du marché(Geithner(2006) et Greenspan(2005)) en permettant le transfert de risque pouvant lui créer une source de perturbation puisqu'ils réduisent la concentration des expositions individuelles des banques ainsi qu'ils favorisent la répartition du risque de crédit plus largement à ces parties.

C'est un point de vue très critiquable puisque d'autres chercheurs démontrent que la faible transparence des CDS a amplifié les phénomènes de défiance et d'incertitude quant à l'exposition globale et la valorisation des produits des principaux intervenants financiers desquels : Brown(2010).Dans ce cas une nouvelle hypothèse est soutenue par la littérature insistant à ce que les CDS ne sont en aucun cas stabilisateurs mais perturbateurs du marché financier. La seule explication de cette contradiction est la différence dans le cadre d'étude en termes de pays et de période.

Une analyse de la littérature sur la relation CDS/Taux d'intérêt d'une dette nous mène à deux types de relations soit une relation négative ou bien positive. Pour le cas d'une relation positive, les taux d'intérêts suivent positivement toute évolution des CDS donc augmentent suite à l'augmentation du recours au CDS et inversement. Ce résultat a été soutenu dans la littérature par plusieurs chercheurs parmi lesquels nous citons : Hirtle(2008), Minton et al(2006), Naifer(2008), Norden et Wagner (2008) et autres.

Contrairement, si nous sommes face à une relation négative, nous devons constater qu'une demande supplémentaire des CDS réduit le coût de la dette. Cette hypothèse a été aussi soutenue par certains travaux tel que Aschcraft et Santos (2009) et Ken Ho-Yu, Yen Yu Hsio & Lo Wen-Chi (2010).

Quel que soit le signe de la relation, nous pouvons confirmer qu'il s'agit bien d'une relation étroite d'arbitrage entre spreads des CDS et ceux des crédits selon les travaux de Duffie(1999) et (Hull et White(2000)). Cette relation est liée à des difficultés énormes quant à la prise de décision de son signe surtout que les chercheurs ne se sont pas mis d'accord sur ce point en présentant des résultats différents.

Notant que la crise a affecté tous les marchés financiers spécialement celui de la dette et celui des CDS. Alors, il reste à analyser si les CDS jouent un rôle de freinage des niveaux des taux d'intérêt en crise ou bien qu'ils aggravent la situation au sein du marché de la dette publique en incitant à une hausse des taux.

Notre travail commencera par la revue de la littérature à la laquelle nous chercherons à détecter la relation théorique entre les CDS souverains et le cout de la dette dans un cadre de crise essentiellement la crise souveraine de la zone euro. Par la suite, nous passerons à une vérification empirique commençant par la méthodologie consistant à la présentation du modèle mettant en relation les spreads de rendements obligataires souverains de la zone euro et les CDS souverains. Plusieurs modèles intermédiaires seront utilisés dans l'estimation par l'incorporation de variables de contrôle. Le choix de ces variables est soutenue par la littérature : Gauthier et Lardic (2003),Norden &Wagner(2008) et Fontana et Scheicher(2016).Ces données sont collectés auprès des sites www.sandpindices.com, www.investing.com, www.global-rates.com et www.stoxx.com.

Enfin, notre travail s'achèvera par la présentation des résultats, la discussion et les conclusions sur le signe de la relation entre les primes de CDS et le cout de la dette publique.

1) Revue de la littérature :

Généralement, les CDS facilitent significativement la commercialisation du risque de crédit lorsque les coûts de financement sont faibles et permettent aux intervenants sur le marché de dépasser des courts risques de crédit aussi facilement que des longs risques de crédit (Longstaff, Mithal et Neis, 2005). Ceci reste vrai dans un cadre caractérisé par des taux d'intérêts faibles donc un cadre de stabilité. Sauf que pendant la crise, le coût de financement s'il est vraiment disponible, il a augmenté en réduisant ou éliminant le retour des arbitragistes (Fontana, 2010).

Sachant bien que suite aux recours aux CDS des liens étroits de dépendance semblent exister entre les entités. Si cette situation s'associe avec le cadre de crise déjà caractérisé de multiplicité des faillites, le risque de détérioration de la qualité de crédit sera beaucoup plus fort et les répercussions des CDS sur le marché de la dette seront plus intenses. Ces répercussions porteront spécialement sur les niveaux de taux d'intérêt. Ce résultat est confirmé par la littérature puisque Cont(2010) affirme que ces produits ont été souvent accusés de porter atteinte à la stabilité financière en période de crise.

Au meilleur de notre connaissance, ils sont rares les travaux empiriques sur la relation entre marché des CDS et coût de la dette obligataire publique pour les pays développés de la zone Euro en crise ce qui explique la complexité de prise de décision quant au signe exacte de cette relation.

Notre étude sera donc tournée vers la détection du rôle joué par les CDS souverains en crise souveraine essentiellement à fin de confirmer ou d'infirmer par la suite d'un travail empirique le caractère déstabilisateur des CDS sur la sphère financière en période de tension.

La crise souveraine est à la base une crise de la dette publique due à une augmentation excessive des dépenses des gouvernements en matière d'aide sociale, de chômage….Ces dépenses sont associées à des destinations non ou peu productrices de richesse au détriment des investissements qui ont été négligé par les gouvernements par pression du cadre social.

Ces dettes ont pesé sur les gouvernements de plus de la conjoncture assez difficile essentiellement suite à la crise financière 2008. Des actions de soutien du système financier associées à une récession économique et une conjoncture défavorable à l'investissement n'ont fait qu'aggraver la situation des pays endettés.

La solution la plus facile pour ces pays était d'augmenter leurs dettes publiques pour trouver les moyens financiers nécessaires pour de tels actes de régulation, ce qui a favorisé **un phénomène de boule de neige de dette gouvernementale.** D'ailleurs, c'est dans les pays dont les finances publiques étaient déjà précaires que la dette a augmenté le plus vite (Boone et als(2010)).Cependant, cela a exigé une augmentation des primes de couverture de ces marchés.

Les premiers signaux de la crise souveraine ont été sentis suite à l'annonce des déficits publics record de la zone euro. Cette annonce a été accompagnée par un mouvement de panique et d'une vision plus sévère du niveau du risque des marchés de la dette publique.

La perception générale de la dette souveraine a été remise en cause par les chercheurs et les intervenants sur le marché financier. Cette dette a été souvent considérée comme une valeur sure, d'ailleurs certains considère qu'elle fuit au risque et qu'elle ne présente aucune source d'inquiétude pour le marché et ses intervenants.

Une idée qui s'est avérée assez loin de la réalité essentiellement dans le cadre de la zone euro ou le déficit budgétaire gouvernemental majoré par un niveau d'endettement élevé des pays à pousser le système financier vers une situation très compliquée.

La phase périodique de ce problème gouvernemental majeur ne fait qu'aggraver la situation. Une phase à laquelle les états ont été obliger de soutenir leurs systèmes monétaires(les banques) en se comportant comme garant ou même en cherchant à les épauler dans leurs combat de survie par la recherche de ressources de fonds propres.

Ces efforts gouvernementaux très poussés en matière de régulation de la crise de la dette publique, la situation reste encore précaire touchant essentiellement la zone euro ce qui suscite l'intérêt de plusieurs chercheurs et intervenants sur le marché financier.

D'ailleurs, selon Dieckmann et Plank(2011), il existe un transfert de risque du privé au public suite aux interventions gouvernementales. Ce transfert est plus important pour les pays appartenant à l'union monétaire européenne que pour les autres.

Ce transfert de risque s'associe à un cadre susceptible de choc et surtout à la favorisation du processus de contagion. Tabak et al(2016), définissent la contagion comme une augmentation de la corrélation entre deux marchés en crise. Donc, une augmentation des niveaux de prix des prix sur un marché s'accompagne par une augmentation imprévue des niveaux des prix sur un autre marché qui lui est corrélé favorisant une transmission imprévue de choc entre les deux marchés(Dungey et al(2004))

Puisque la crise souveraine de la zone euro était plus prévisible que la crise des subprimes (Hsiao et Morley(2015)), les intervenants sur le marché de la dette souveraine ont cherché une source de sécurité ce qui a favorisé le développement du marché des CDS souverain suite à la crise. Selon Olléan-Assouan(2004), les CDS souverains sont nés de l'intérêt des investisseurs pour une couverture préventive du risque pays.

Ces produits forment un marché relativement restreint par rapport à celui des obligations. Cependant, plusieurs chercheurs considèrent que le marché des CDS reflète parfaitement la situation du marché. D'ailleurs, ils considèrent qu'il est capable de donner des signaux préalables à un incident de défaut. Ainsi, les spreads des CDS présentent une bonne source de données pour tester la contagion puisqu'ils servent de mesure des probabilités de défauts (Kalbaska et Gatkowski(2012)).

Les chercheurs ont longtemps considéré qu'il n'existe pas de différence entre spreads de CDS et ceux des rendements d'obligations souverains. D'ailleurs, à ce sujet Duffie(1999) et Hull and White(2000) ont trouvé une relation de parité entre spreads obligataires et spreads des CDS dans le cas d'absence d'opportunité d'arbitrage. Pourtant, d'autres considèrent qu'ils existent des différences entre les deux spreads (Dellate et al (2011))et (Mithal et Neis(2003))

Théoriquement, ce sujet est à présent un centre débat surtout avec les évolutions conjoncturelles récentes. D'ailleurs plusieurs chercheurs ont analysé l'existence et le signe de la relation entre spreads de CDS et ceux de la dette obligataires. Hull, Prescu et white (2004) démontre que cette relation existe de même pour Dellate et al (2011) qui insistent à ce que qu'on doit être dans le cadre de mêmes entités de mêmes maturités.

Ainsi, Giovanni Calice et al (2011) trouvent qu'il est possible de considérer l'existence d'une relation de causalité entre l'augmentation des spreads obligataires et ceux des CDS pour la majorité des pays fortement touchés par la crise (Grèce, Portugal et Ireland).Ce point de vue est soutenue par Norden et Weber (2004), Blanco et al (2005),Zhu(2006) et Baba et Inoda(2007) qui considèrent que les innovations sur le marché des CDS ont tendance plus grande à se répercuter sur les spreads obligataires que l'inverse.

Une confirmation soutenue par le travail de Coudert et Gex(2010) qui estiment que le marché des CDS devance le marché obligataire même hors de périodes destinées à la baisse (hors crise).De même, pour Blanco, Brennan et Marsh(2005) qui estiment que le processus de découverte de prix de passe toujours sur le marché des CDS.

Notant que les CDS souverains sont encore loin d'être assez compétitifs face aux CDS corporate .Cela est due à la taille de ce marché qui reste encore très réduite à cause de la perception générale du niveau de risque des gouvernements qu'on considérait inexistants ou très réduits. Cette vision du risque fait que le volume total des dettes publiques protégées via CDS souverains est encore très loin du volume total des dettes souveraines sur le marché contrairement au marché de CDS corporate qui est plus grand que le marché de la dette auquel il est attribué grâce au phénomène d'accumulation de contrats.

L'impact de l'échange des CDS souverains sur l'évolution du coût d'une dette a commencé à susciter de l'importance et de l'intérêt des chercheurs avec le développement des volumes des transactions sur ces marchés. Brunnermeier et als(2013) estiment que les liens existants entre spreads des CDS et spreads obligataires peuvent par le phénomène de « la queue qui agite le chien », aboutir à la propagation de chocs partant des marchés des dérivés vers les marchés au comptant augmentant ainsi les couts de financement.

La plupart des études antérieures sur ce sujet (Blanco, Brennan et Marsh (2005),……..) ont démontré que les spreads des CDS influencent les spreads de crédit. Dans ce cas, c'est très intéressant de voir si l'effet provoqué

par ce type d'engagement s'avère positif ou bien négatif sur le marché de la dette publique surtout en période de crise caractérisée déjà d'augmentation des niveaux de risques et de craintes des défaillances.

La phase actuelle à savoir celle d'une crise souveraine de la zone euro, nous a incité à tester la relation entre spread des CDS et spread des rendements obligataires souverains de la zone Euro.

Ainsi, la détection du signe de cette relation nous indiquera le pouvoir d'influence des CDS sur la stabilité de marché financier et le redressement du cadre de la dette publique. Ainsi l'impact de ces produits sur le cout de la dette publique.

2) Méthodologie :

Notre travail portera sur la zone euro. Ce choix est expliqué par la période à laquelle fait face cette zone. Une période caractérisée de stress et de pression énorme due la crise de la dette publique.

Cette crise souveraine a commencé à prendre de l'ampleur et d'être un sujet d'inquiétude dès les débuts de l'année 2010 ce qui explique notre choix de la période d'étude à savoir **du 22 mars 2010 jusqu'au 22 février 2016 sous forme de données journalières.**

L'objet de cette partie empirique est de répondre à la question : **Est-ce que le recours au marché des CDS affecte négativement le cout de la dette publique en période de stress ?**

Afin de répondre à cette question nous estimerons le modèle de régression linéaire suivant :

$\Delta crédit\ souverain_t + = \beta_0 + \beta_1 \Delta crédit\ souverain_{t-1} + \beta_2 \Delta CDS_{t-1} + \varepsilon_t$

$\Delta crédit\ souverain_t$ = représente les évolutions des spreads des rendements de la dette obligataire souveraine à la date t

$\Delta crédit\ souverain_{t-1}$=représente les évolutions des spreads des rendements de la dette obligataire souveraine à la date t-1

ΔCDS_{t-1} = représente les évolutions des spreads des CDS souverains à la date t-1

ε_t= représente le terme d'erreur

Il s'agit du modèle de base **(modèle 1)** à partir duquel nous chercherons à comprendre la relation entre les spreads des obligations souverains et ceux des CDS après avoir présenté au cadre de la partie théorique la relation entre spreads de crédit et les évolutions du taux d'intérêt.

Plusieurs autres modèles auxiliaires seront mises en place à fin de répondre à notre problématique. Tout d'abord, nous chercherons à voir l'impact des autres variables de contrôle sur les spreads de la dette obligataire souveraine en commençant par la variable « indice de prix à la consommation harmonisé » et en ajoutant les autres variables présentés dans le tableau suivant une par une.

Tableau 1: Les variables utilisées :

Variable	Définition
Crédit souverain	Spreads de rendement des obligations souveraines
CDS	Spreads des CDS souverains
IPCH	l'indice des prix à la consommation harmonisé de la zone euro
CHANGE	le taux de change : Euro/dollar
EUROSTOXX	un indice boursier européen

Enfin, nous ajouterons à nouveau la variable " spreads des CDS" pour voir l'impact de cette variable en présence des autres variables macro-économiques du marché de la zone euro.

Nous commencerons en premier lieu dans le cadre d'un deuxième modèle **(Modèle 2)** par le test de la relation entre indice de prix à la consommation harmonisé et les spreads de la dette obligataire souveraine.

Par la suite nous ajouterons une autre variable au deuxième modèle qui est les évolutions du taux de change Euro/dollar pour former le troisième modèle **(Modèle 3)**. Puis, nous ajouterons à ce dernier la variable « évolution d'un indice boursier européen Eurostoxx »dans le cadre d'un quatrième modèle **(Modèle 4)**.Ce modèle regroupera toutes les variables macro-économiques et essaye de voir l'impact de ces variables sur les évolutions des spreads de la dette obligataire souveraine de la Zone Euro.

Pour mieux comprendre l'impact des évolutions des spreads des CDS sur les spreads de la dette obligataire souveraine, nous ajouterons au quatrième modèle la variable explicative de base "évolutions des spreads des CDS" pour former un cinquième modèle **(Modèle 5)**.

Nous nous concentrerons essentiellement sur deux modèles dans notre analyse qui sont le premier et le cinquième modèle pour cerner le rôle exacte des CDS tout seul sans prise en compte d'autres variables et avec prise en compte des variables macro-économiques du marché et effectuer par la suite une comparaison entre les deux cas.

Dans le cadre de cette partie nous tenterons d'accepter ou de rejeter l'hypothèse suivante : **Les évolutions sur le marché des CDS favorisent la déstabilisation du système financier en augmentant les engagements publics en termes de taux d'intérêt**

Le taux d'intérêt d'une obligation suit une relation inverse aux évolutions des spreads de des rendements obligataires donc il augmente lorsque ce dernier diminue et diminue inversement.

Une relation positive ($\beta_2 > 0$) entre spreads souverains et spreads des CDS signifie que le recours au marché des CDS se traduit par une augmentation des spreads de la dette souveraine. Ces derniers sont reliés inversement au taux d'intérêt. Dans ce cas, un recours au marché des CDS augmente les spreads de rendements de la dette souveraine et réduit le coût de la dette publique.

Par ailleurs, une relation négative ($\beta_2 < 0$) entre spreads de la dette obligataire souveraine et spreads des CDS signifie que le recours au marché des CDS se traduit par une diminution des spreads souverains. Ces derniers sont reliés inversement au taux d'intérêt. Dans ce cas, un recours au marché des CDS réduit les spreads de rendement de la dette publique et s'accompagne par une hausse du coût de la dette publique.

Nous pouvons conclure alors que si $\beta_2 < 0$ on accepte H

Sinon on rejette H

3) Résultats et discussions :

Après avoir effectué le test de stationnarité nous avons trouvé que seule la variable crédit souverain est stationnaire à niveau. Pour les autres variables, ils ne sont stationnaires qu'en différence première.

Tableau 2 : Les résultats de l'estimation par MCO du modèle de base et de ses extensions.

	Modèle de base		**Modèle2**		**Modèle3**		**Modèle4**		**Modèle5**	
	Coef	Prob	Coef	Prob	Coef	Prob	Coef	Prob	Coef	Prob
d(crédit souverain(-1))	-0.222846	0.0***	-0.222118	0.0***	-0.221931	0.0***	-0.222073	0.0** *	-0.222764	0.0***
d(CDS(-1))	-0.006866	0.5265							-0.006818	0.5305
d(ipch(-1))			0.000725	0.9923	-0.001378	0.9856	0.001397	0.9870	-0.000651	0.9941
d(change(-1))					0.000459	0.9477	0.000479	0.9464	0.000178	0.9806
d(eurostoxx(-1))							2.93E-07	0.8599	2.76E-07	0.8698
Obs	1480		1583		1554		1523		1478	
R squared	0.049643		0.049336		0.049273		0.049386		0.049663	

* :significative pour 10%

** :significative pour 5%

*** :significative pour 1%

Pour le modèle de base *:*

La variable $\Delta crédit\ souverain_{t-1}$ a un effet négatif est significatif à l'ordre de 1% par contre la variableΔcds_{t-1} a un effet négatif mais non significatif.

Pour le modèle 5(Extension avec prise en compte de la variable CDS) *:*

Seule la variables $\Delta crédit\ souverain_{t-1}$ est significative respectivement à l'ordre 1%.Pour les autres variables, Δcds_{t-1} et $\Delta ipch_{t-1}$) ont un effet négatif et non significatifs contrairement aux variables $\Delta eurostoxx_{t-1}$ et $\Delta change_{t-1}$ qui ont un effet positif.

En appliquant le test de white, nous avons trouvé que la probabilité est égale à 0.0000 qui est largement inférieur à 0.05 donc les erreurs sont hétéroscédastiques. De point de vue corrélation, le test de Durbin Watson indique une valeur de 1.988519. Ce résultat signifie qu'il n'y a pas d'autocorrélation des erreurs

Pour l'analyse de la normalité des erreurs, le coefficient du degré d'asymétrie de la distribution (skewness) est égal à -14.97527 .La distribution décalée à droite de la médiane, et donc une queue de distribution étalée vers la gauche.

Ainsi le coefficient d'aplatissement (kurtosis) mesurant le degré d'écrasement de la distribution est égal à 432.9578. Dans notre cas la distribution est plutôt pointue (leptokurtique).Quant à la probabilité associée au test de Jarque Bera (0.00000), elle est inférieure à 0.05 ce qui implique qu'il n'y a pas normalité des erreurs.

Tableau 3 : Les résultats issus de la comparaison entre le modèle de base & l'extension du modèle avec prise en compte de la variable CDS :

	Modèle de base		**Modèle avec extension**
β_2	-0.006866	<	-0.006818
R squared	0.049643	<	0.049663

Le coefficient des évolutions des spreads des CDS souverains β_2 est négatif donc on accepte l'hypothèse que ce soit dans le modèle de base ou le modèle d'extension(modèle 5) ce qui fait qu'il existe une relation négative entre les évolutions des spreads des dérivés sur défaillances(CDS) et les évolutions des spreads de dette obligataire souveraine.

Ce résultat signifie qu'une augmentation des spreads des CDS souverains (donc une augmentation du coût de la protection via CDS) réduit les spreads des rendements des obligations souveraines.

Les prix des CDS souverains augmentent avec l'augmentation de la demande de ces instruments sur le marché suivant ainsi la loi de l'offre et de la demande. Par conséquent, le recours aux CDS (exprimé par l'augmentation de la demande) augmente les prix de ces derniers et augmente parallèlement les taux d'intérêt sur le marché de la dette.

Le non significativité des résultats peut être expliqué par la différence énorme entre marché de la dette obligataire publique et marché des CDS souverains en termes de taille. Ce dernier reste un marché émergent et donc de taille faible par rapport au marché de la dette publique assez développés surtout suite à la crise des subprimes.

En comparant les deux modèles nous remarquons que la qualité d'ajustement s'améliore avec la prise en compte des autres variables macroéconomiques. Quant aux relations de ces derniers avec les évolutions des spreads de la dette obligataire souveraine, ils seront analysés dans le cadre du tableau suivant.

Tableau 4 : Synthèse des résultats des variables de contrôle

Variables	**Evolutions attendues**	**Résultats MCO**
EUROSTOXX	+	+
CHANGE	+	+
IPCH	-	-

En cas de recours au marché de la protection via CDS, la demande de ces produits va augmenter donc les primes demandées pour les détenir vont augmenter de même. Ce phénomène s'est dévoilé suite à la crise des subprimes en 2008 et s'est accentué avec la déclaration des déficits des pays par la suite d'un niveau de dette publique énorme. D'ailleurs le marché des CDS souverains qui était très réduits jusqu'à 2010 a commencé de s'agrandir par la demande de protection en hausse suite à la réalisation des niveaux des risques élevés sur les marchés monétaires et financiers surtout le risque souverain qui était sous-évalué par les intervenants de marché pour longtemps et qui s'est déclaré présent et menaçant pour toute la zone Euro.

L'augmentation des niveaux de risques sur le marché est associée à une perception plus exigeante des acheteurs d'obligations publiques qui seront plus strictes en matière de rendements exigés .Ils exigeront un rendement supérieurs pour accepter de supporter un nouveau niveau de risque d'Etat qu'ils estiment supérieur.

Ces nouvelles exigences se répercutent surtout sur les niveaux de taux d'intérêt reliés aux obligations. D'ailleurs, la nouvelle rémunération des obligations devra être supérieure parallèlement au risque en hausse.

Cette augmentation des taux pèsera sur les états émetteurs d'emprunts obligataires et donc constituera une charge supplémentaire pour ces pays qui sont déjà en crise de surendettement.

Les CDS souverains ont donc contribué à enfoncer les déficits des pays de la zone euro et à masquer la vraie facette de risque du marché. L'effet crise a divulgué le vrai risque fournit par cet outil de couverture. Il a permis donc de changer la perception vis-à-vis de cet instrument.

Conclusion :

Nous pouvons donc conclure que les CDS n'ont pas joué le rôle attendu en crise soit l'atténuation des niveaux de risques des Etats. Au contraire, ils ont présentés une source de déstabilisation puisque l'agrandissement de leur marché a favorisé l'accroissement des couts en termes d'intérêt sur les obligations souveraines. Cet effet déstabilisateur du marché favorisé par les CDS est expliqué par les problèmes reliés à ce marché.

Ces produits ont créé un terrain favorable à l'émergence de la crise par leur caractère très opaque et ils ont aggravé en quelques sortes la situation du marché dans cette période. D'ailleurs, comme nous l'avons déjà montré, l'interaction de ces produits avec le marché de la dette en crise a favorisé une mauvaise estimation des perturbations futures du marché.

Nos résultats convergent avec les résultats d'Ashcraft & Santos(2009) qui ont trouvé que dans la majorité des cas le recours au marché des CDS ne permet pas la réduction du coût de financement de la dette malgré les différences en termes de cadre d'étude entre crise hypothécaire et souveraine et de marché étudié entre marché de dette bancaire et publique. De même, Hirtle(2008) a trouvé que bien pour les petits que grands emprunteurs, l'effet d'un accroissement de la protection via dérivés de crédit a un impact négatif sur les nouvelles dettes. Donc, il permet l'augmentation des coûts qui leurs sont reliés.

Les CDS qu'on considérait capables d'alléger le déficit des pays par l'amélioration des prévisions de stabilité des marchés obligataires et donc l'atténuation des couts associés à ces dettes, n'ont fait que creuser les déficits des pays. Ils n'ont pas été à la hauteur des attentes des marchés surtout sur le plan informationnel. A ce sujet, Longstaff, Mithal et Neis(2005) considèrent que les spreads des CDS présentent une information pour la mesure de défaut. Une mesure dont l'évaluation a besoin d'être révisée pour une meilleure estimation des risques de marché et une meilleure prévision des possibilités de contagion de chocs entre les marchés.

Abstract

The complex business world faces global challenges that make difficult to create business as well as survive and grow up at the same time. In Mexico most of its companies are micro, small and medium-size that constitute an important contribution to the gross domestic production and the employment creation. The study of economic and financial factors that influences the growth with the purpose of identify strategies that allow the sustained growth of smaller companies. The progress of this work up to today is the literature review and the methodological design for the accomplishment of the objectives.

Keywords: sales growth, financing, age, size.

Introduction

Researches on entrepreneurism growth has been increasing according to bibliometric analysis WoS ISI 1980 until March 21, 2016, exist 356 documents among articles, proceedings papers, book chapter and review ; which in their titles include "business growth" . There are two researches of Mexico, the first includes the importance of government support through access to finance, technology and strategic alliances in subsistence enterprises and the Second one is an analysis of the sources of asset growth of large multinational companies located in Mexico, (Toledo, A., Hernandez, J. D., and Griffin, D., 2010).

In the country the size of business is established according to the Official Gazette published on June 30, 2009; this work is considered the criterion the range of number of workers. 99.8% of economic units are Micro, small and Medium (Mipymes), employ the 71.20% of workers and participate with

the 35.90% of gross production. Bigger companies contribute with 64.10% of gross production and generate the 28.80% of employment; we denote the economic and social importance of smallest enterprises, as well as the importance in the gross production of the biggest ones, according to data published by the National Institute of Statistics and Geography (INEGI, 2014).

On the other hand, the life expectancy of companies in Mexico, depends on how long they have been in business. Newly created businesses have a probability of existence of 7.7 years and those 20 years old have a life expectancy of 21 years. It is showed that as older is greater life expectancy. Mexican Mipymes nationwide that survived were 78%; grew 6.3%, for every 100, there are 6 more between 2009 and 2012, INEGI, (2013). So, we notice that growth is an important phase of the life cycle in a lucrative company.

Therefore it is interesting to analyze the causes that explain that some companies stay longer than other ones. The main objective is to understand the key economic and financial factors that contribute to sustained business success that enhance growth in Mexican companies. To this end, they analyze companies that obtained higher growth in sales at the end of 2015, according to financial information published in Expansion magazine and software Economatica of Mexico. It is planned to analyze the factors affecting the growth of big business and how its capabilities can be implemented by smaller companies in such a way that allows them to consolidate and grow (Fuentes, C.D., 2008: pp. 27-28).

Preliminary results of the review of the literature realize that the variables that affect the sales growth are among others: macroeconomic analysis based on the neoclassical model, size, age of the company, economic sector, the nature of the property, capabilities and resources, the sex of their owners or managers, market financing equity and private debt of small businesses as well as optimal capital structure in different parts of the cycle, external business advice, high technology, innovation, skill level of the workforce, export, (King, R. G., Plosser C.I., and Rebelo S.T., 1988; Cliff, J. E. 1998; and N. Berger, A. and G. F. Udell, 1998; Robson, P.J.A and R.J. Bennett, 2000). Other research is related to the construction of an integrated model for small business growth (Wiklund, J., H. Patzelt, H., and Shepherd, D.A. 2009). Business growth is measured through the increase in total

assets, sales, revenues, costs, financing, number of employees, net investment, leadership, corporate culture, (Blazquez, F., Dorta, J.A. and Verona, M.C., 2006; Amat, O. and Lloret, P., 2014).

For these reasons, the hypothesis is about the sales growth with the implementation of flexible business models revenues, costs, investments and financing, along to strong values such as culture, innovation, technology, export, consultancy, efficiency, sex owners or managers, size, age and economic sector.

The methodology is mixed and is based on three main lines of work:

1. Case studies of higher growing companies, using grounded theory through comparative documentary analysis of annual reports, through matching qualitative variables, with Atlas Software Textual Ti.

2. Calculation of regression analysis least squares in two phases and the logarithmic decay based on quantitative methodology of relations between independent and dependent variables.

3. Design of a comprehensive model for the growth of Mexican MSMEs based on the application of surveys to a representative sample, in order to identify economic and financial factors that affect the sales growth of this size of companies, containing the variables according to the literature review as well as those resulting from points 1 and 2 above.

This project is funded by the Universidad Autonoma de Sinaloa in Mexico through the Program Development and Research Project Support (PROFAPI 2014).

Technical Reserves in Insurance

Ing. Jozef Adamko,PhD.,MBA, School of Economics and Management of Public Administration in Bratislava, Slovakia, jozef.adamko @vsemvs.sk
Ing. Emil Burák,PhD., School of Economics and Management of Public Administration in Bratislava, Slovakia, emil.burak @vsemvs.sk

Abstract

For the basic characteristics calculation the mathematical-statistic methods are used. For the trend function parameter estimate the smallest square method known from the regression analysis is used. The source of analysis is the data set published by the National Bank of Slovakia from years 2004 – 2014. Based on the thesis results we can state that in the life insurance the growth of the technical insurance continues, on the other hand the structure among various sectors has changed. In the non-life insurance the negative trends continue in car insurance.

Keywords: insurance market, macroeconomic indicators, insurance, prediction

Introduction

These resources represent a process of placement of temporarily available financial resources to the financial market for the purposes of their return and profit generation. Insurance companies therefore handle such property very carefully because it is covered from these technical reserves serving for coverage of risks of insurance and coverage activities. It is therefore suitable to establish certain limitation concerning unrestricted usage of such property to avoid devaluation of these technical reserves, which is also governed by the Act on Insurance.

1 Resource Placement Structure of the Technical Reserves in Insurance

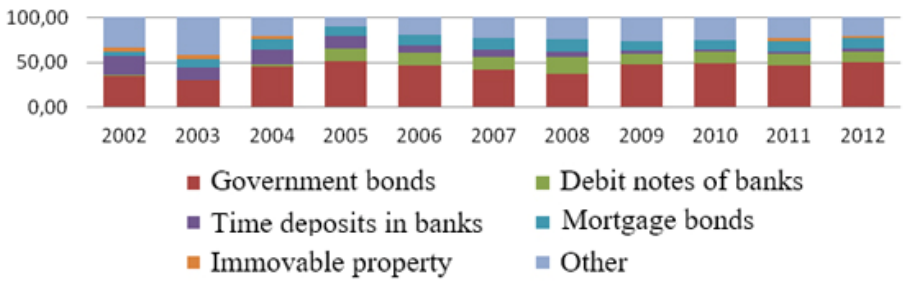
In ten-year time evaluation of the technical reserves, which we have observed from statistical bills, we have discovered following results, which are described in greater detail year after year until their final form.

To 31.12.2004, the insurance companies created the technical reserves[1] in the total amount of EUR 1,70 bil, which corresponded to year-on-year growth of 11,56%. Out of which, the technical reserves in life insurance were created in the amount of EUR 1,37 bil and the technical reserves in non-life insurance in the amount of 333,3 bil. The technical reserves in the life insurance increased in year-on-year growth of 13,94%, in the non-life insurance, the technical reserves increased in year-on-year growth of 2,72%.

To 31.12.2006, the value of 3,44 bil, which corresponded to year-on-year growth of 15%. The reserves of the life insurance reached the value of almost 2,52 bil corresponding to 73% of the total technical reserves. Net technical reserves of the insurance companies reached the value of EUR 3,15 bil to 31.12.2006.

Technical reserves deducted by the reserved for the coverage of the obligations from the financial placement on behalf of the insured parties reached.

Structure of the placement of resources of the technical reserves (%)



Source: Authors' own elaboration according to the data of the NBS.

Figure 1 Structure of the placement of resources of the technical reserves in the Slovak Republic over the 2002 – 2012 period in %

To 31.12.2009 the amount of EUR 4,47 bil. Technical reserves of the insurance companies increased during 2009 by 11,3%. The principal source of increase was the life insurance, in which the reserves reached the value of 3,45 bil and in the non-life insurance; they reached the amount of EUR 1,02 bil.

Technical reserves reached the amount of EUR 3,78 bil by the end of 2009. The coverage of the technical reserves by the actives increased to 112%. The insurance companies increased particularly the holdings of government bonds and decreased their exposure to bank bonds and time deposits. [2]

By the end of 2010, insurance companies generated the technical reserves in the amount of EUR 4,66 bil. In comparison with the previous period, they increased by 7,2%, whereby the growth rate was slower mainly due to a slower growth of the technical reserves in the life insurance.

By the end of 2011, the total amount of the technical reserves of the insurance sector decreased to EUR 4,64 bil. This decrease was historically the first of the total volume of the technical reserves in the observed period.

The decrease was caused mainly due to the development in the non-life insurance, in which the reserve for the insurance fulfilment decreased by 9% year-on-year (by 67 bil). On the contrary, the reserve for the insurance fulfilment increased by almost 16 bil due to continual contract conclusion to technical year and not to calendar year.

After the drop in 2011, total technical reserves of the insurance companies started to grow again in 2012 and reached 4,86 bil. Even though the reserves in life insurance continued in a continual growth, they decreased again in non-life insurance similar to 2011.

In life insurance, the development was caused particularly by the growth of the reserve in unit-linked insurance, which grew year-on-year by 147 mill. (17%). More than a half of this growth was caused by the growth of deficit reserve created on the basis of the test of sufficiency of the reserves, which increased by 52 mill. Growth of this reserve is probably linked to decrease in interest rates.

In non-life insurance, the technical reserves decreased year-on-year by 27 mill. All types of reserves in the non-life insurance decreased, whereby the biggest impact had a decrease of the reserve on insurance fulfilments, which dropped by 17,5 mill. It is important that this reserve reflects real estimate of the risk and that it is not artificially decreased by the insurance company.

Actives covering technical reserves, except for the reserves for the coverage of obligations from the financial placement on behalf of the insured (RKZFUMP) reached almost 4,6 bil by the end of 2012, whereby their volume increased by 251 mill. Coverage of the technical reserves by the actives increased to 119%.

The biggest increase corresponds particularly to government bonds, from which the majority is covered by the Slovak bonds. Volume of the bonds increased mainly due to the overpricing of the bonds in portfolios for sale and for business. The ratio of the government bonds in actives covering the technical reserves therefore increased to almost 50%. The ratio of other classes of the actives decreased, except for the time deposits, the volume of which increased year-on-year by 56% (by 60 mill.) and substituted part of the company bonds, volume and ratio of which dropped. Share of reinsurers on technical reserves, volume of immovable property, shares and units is gradually falling.

In 2008, financial situation of the majority of insurance companies worsened in comparison with the previous year. The total profit of insurance companies decreased by almost a half and reached the amount of EUR 108 mill. The return of their equity dropped from 18,8% to 8,9% in 2007. The period of significant growth of profitability observed from 2003 stopped.

Negative development on financial markets was influenced by the profitability of actives, mainly by bigger insurance companies. The profit generated from the financial operations decreased by more than 76% in comparison with 2007. If we abstract from the unit-linked products, financial results of the insurance companies dropped by 39 mill. (i.e. 23%) in comparison with 2007, mainly as a result of lower profitability of the actives of the insurance companies.

Despite the unfavourable development of the insurance in 2008, which resulted in lower technical result, the total financial situation of the insurance sector improved in comparison with the previous year, since year-on-year decrease on the technical account was compensated by the increase of profits from the financial operations.

The increase of profits of the entire sector was crucially influenced to the greatest degree by the increase of profits of the three biggest insurance companies.

These values, as well as the total profit of insurance companies, however, were falling behind the values from 2006 and 2007.

In 2009, five insurance companies reported a loss, two less than in the previous year. [3]
In 2010, the total amount of profits of the insurance sector fell by 2,9% to 133,7 mill. after the previous more significant growth. One insurance company influenced crucially this result.

Technical result reached 127 mill. of the previous year's loss of 75 mill., which was the highest value in history. An improvement occurred in large-scale with all insurance companies. The technical results in the life insurance improved by EUR 140 mill., in the non-life insurance by EUR 56 mill. and in the active insurance by EUR 6 mill.

Improvement of the technical result was caused mainly due to decrease of loss ratio in property insurance, increase in earned premium in life insurance and decrease of deficit reserve on the basis of the test of sufficiency of reserves. The technical results were also improved by a significant decrease in reserve growth for unit-linked products by 95 mill., which development was, however, almost totally compensated by the decrease of the financial result of actives covering unit-linked reserve. The drop of the financial result was caused almost entirely by unit-linked insurance.

However, the development of the profitability was various, with the two thirds of insurance companies the profitability increased year-on-year. In 2014, two insurance companies ended with loss.

The profit was generated mainly by the financial result and positive technical result in non-life insurance, whereby the technical result in life insurance was negative.

The major development was observed on technical account of life insurance, which year-on-year decreased from EUR 43 mill. to -175 mill. The decline occurred at almost all insurance companies. This development was influenced by several main factors: unit-linked insurance, deficit reserve, moderate growth of insurance and growth of costs on insurance fulfilments.

In 2014, financial result rose by EUR 134 mill. and reached 300 mill. due to positive development on the financial markets, from which the financial result of the investments, where the risks are borne by the client increased by 135 mill. (increase at almost all insurance companies) and of the investments, where the risks are borne by the insurance by 28 mill. The financial result was positive at all insurance companies, even though approximately a third of the insurance companies reported year-on-year fall of the financial result.

The technical result in non-life insurance was positive at the average level for the last 5 years. Four of thirteen insurance companies reached negative technical results from non-life insurance.

It can be concluded that the profitability of the insurance sector has not changed significantly in the last five years and has remained sufficient.

By the end of 2014, solvency of the insurance companies significantly increased due to the profits from re-evaluation of the commercial papers in the portfolio for sales.

However, due to the falling interest rates, these profits serve only as a pillow in case of growth of interest rates

In the future, insurance companies should create reserves for losses from overestimation due to the growth of interest rates for the bonds, which are currently purchased into their portfolio.

2 Prediction of the Technical Insurance by Time Series

In order to identify the trend, we considered three basic types – linear, quadratic and exponential. By their application to the area of the technical insurance in the life and non-life insurance, we have obtained following results for the trend functions:

Table 1 Identification of the trend in the area of life and non-life insurance in the SR in the period 2004 – 2014

	Life insurance
Linear trend	$y_i = 0{,}488364 + 0{,}0652727i$
Quadratic trend	$y_i = 0{,}337455 + 0{,}134923\,i - 0{,}0058042\,i^2$
Exponential trend	$y_i = \exp(-0{,}646272 + 0{,}0806684i)$

	Non-life insurance
Linear trend	$y_i = 0{,}835636 + 0{,}0143636i$
Quadratic trend	$y_i = 0{,}657455 + 0{,}0966014\,i - 0{,}00685315\,i^2$
Exponential trend	$y_i = \exp(-0{,}191362 + 0{,}0175186i)$

Source: Authors' own elaboration according to the data of the NBS.

Technical insurance in the life insurance shows growing tendency and moderately declining tendency in the non-life insurance.

According to the importance of the coefficients, we gave preference to the model containing linear trend. While choosing the appropriate model, we considered the following:

Importance of the coefficients,

Autocorrelation of residuals (tested by Ljung-Box test),

Akaike information criterion.

Following table shows basic characteristics (first differentia and growth or decrease coefficient.

Table 2 Basic characteristics of the technical insurance in the area of life and non-life insurance in the SR in the period 2004 – 2014

		Life insurance			Non-life insurance		
i	Year	y_i	${}_1d_i(y)$	$k_i(y)$	y_i	${}_1d_i(y)$	$k_i(y)$
1	2004	0,52	xxx	xxx	0,69	xxx	xxx
2	2005	0,57	0,05	1,1	0,83	0,14	1,2
3	2006	0,64	0,07	1,12	0,95	0,12	1,14
4	2007	0,74	0,1	1,16	1	0,05	1,05

11	2014	1,11	0,02	1,02	0,92	-0,03	0,97

Source: Authors' own elaboration according to the data of the NBS.

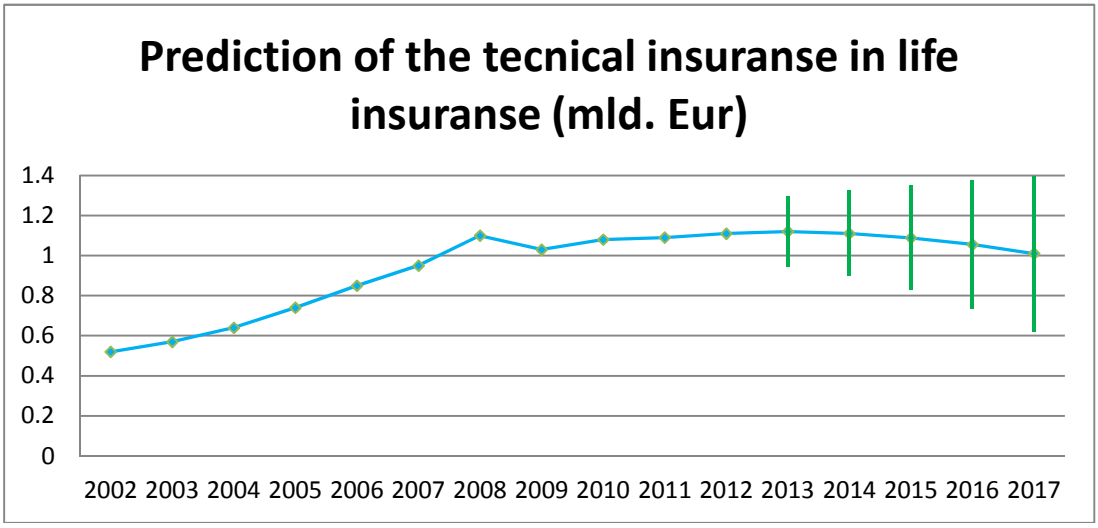
To conclude, from the model above, we have elaborated a prediction for the following five years. The results are shown in the following table and figures:

Table 3 Prediction of the technical insurance in the area of life and non-life insurance in the SR for the period 2013 – 2017

		Life insurance			Non-life insurance		
i	Year	y_i	Confidence interval 95 %		y_i	Confidence interval 95 %	
12	2013	1,12073	0,953648	1,28781	0,887733	0,765947	1,00952
13	2014	1,11055	0,905916	1,31518	0,887733	0,627925	1,14754
14	2015	1,08876	0,835432	1,34208	0,887733	0,541079	1,23439
15	2016	1,05536	0,743157	1,36756	0,887733	0,471996	1,30347
16	2017	1,01035	0,629864	1,39084	0,887733	0,412858	1,36261

Source: Authors' own elaboration according to the data of the NBS.

According to the analysis of the Slovak financial sector for the first half of the year 2013[4] in the sector of insurance companies, it is stated that the growth of the technical insurance accelerated year-on-year only moderately from 0,8% to 1,3% in the first half of the year 2013. The total amount of the technical insurance in the observed period reached EUR 1,07 bil, which corresponds to the prediction for 2013 (app. EUR 2,00 bil)



Source: Authors' own elaboration according to the data of the NBS.

Figure 2 14, 95 % prediction of the technical insurance in life insurance in the SR for the period 2013 – 2017 in EUR billions.

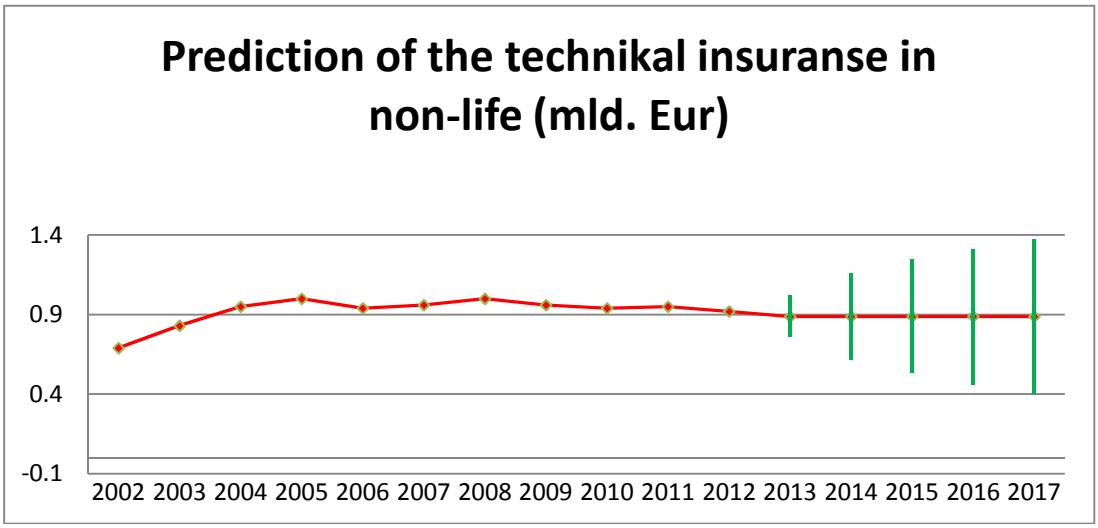
According to the abovementioned analysis of the first half of the year 2013, the growth of the technical insurance was influenced by the life insurance with the technical insurance in the amount of 0,57 bil. (3,8% growth year-on-year), mainly the common life insurance and the complementary insurance.

In comparison with the previous periods, the most significant change is represented by the decrease of the technical insurance of the investment insurance products, so-called unit-linked insurance, constituted by year-on-year decrease by 4,6% to the amount of 171 bil. The share of the unit-linked products on the insurance market dropped under 30%. Annual insurance, including new production, reported year-on-year decrease by 11,2% or 14,8%. However, despite this fact, the new production continues to represent a major part, almost 15% of the annual insurance. Slower growth of the insurance contracts in the unit-linked sector was influenced also by a growing number of insurance fulfilments due to surrenders and survival benefits, even though the growth rate was slowing down. The frequency of surrenders was at the level of 6,2% (5,9% in June 2012) and year-on-year growth of the surrender cases decreased from 20% to 6,5%.

The total amount of surrenders corresponded to 4,5% of the technical reserves in unit-linked sector (4,9% in June 2012). In contrast with the unit-linked insurance, the common life insurance reported positive growth in the technical insurance after two years of decrease in the first half of the year 2013. In June 2013, the amount of the technical insurance reached 314 bil, which corresponded to year-on-year growth of 7,6%.

The volume of insurance fulfilment in the first half of the year 2013 was in the amount of 292 mill., which corresponded to year-on-year growth of 7% (mainly surrenders, similarly to the case of unit-linked insurance), which accelerated the sector in comparison with the same period of the previous year by 4 percentage points. The number of insurance fulfilments dropped for more than 7%.

On the other hand, the non-life insurance continued in negative trend in the area of the technical insurance (0,5 bil, decrease of 1,5 % year-on-year). This development was influenced particularly by the liability insurance and car insurance. The real values of the first half of the year 2013 showed the validity of the prognoses.



Source: Authors' own elaboration according to the data of the NBS.

Figure 3 Again 15, 95 % prediction of the technical insurance in non-life insurance in the SR for the period 2013 – 2017 in EUR billions.

Technical insurance in the non-life insurance from 2009, except for 2011, was dropping. This development was influenced mainly by the car insurance in the first half of the year 2013.

The most significant drop of the technical insurance, represented by 7,5 mil. to 147,4 mil. (-4,9 % year-on-year), was observed with the liability insurance. This development was influenced by the long-lasting decrease of the insurance amounts of new (-4,7 % year-on-year) and prolonged contracts (-6,3 % year-on-year). Growth of the

insurance contract numbers slowed down in the first half of the year 2013 (2,1 % year-on-year), however, in comparison with 2012, new production transformed from contraction of -10,7% to expansion of almost 5%. Although the number of claims dropped year-on-year by approximately 6,5%, the total amount of the claims increased by almost 4%.

The technical insurance in the area of the collision coverage on the level of 124,5 mill. showed, similarly to the liability insurance, a year-on-year decrease, which slowed down from -5,5% in June 2012 to -3,8% in June 2013. The average insurance for one contract was falling down in particularly new production (-10,4% year-on-year, in June 2013, the decrease represented -18,9%). The decrease of the average insurance price for one contract was slightly less aggressive in prolonged contracts (-5,2 %), however, in comparison with 2012, it accelerated (in June 2012 decrease of -2,2 %). In the observed period, the number of the insurance fulfilments increased significantly (7% year-on-year) and predominantly their volume (10,5% year-on-year).

The development of the technical insurance and volume of costs for the insurance fulfilments in the area of collision insurance had a negative impact on the technical result. A particularly high loss ratio and continual reduction of the insurance pushed the combined index in the collision insurance over the edge of 100%.

In the area of the property insurance, the technical insurance grew year-on-year only moderately, on the level of 1,6% and reached the amount of almost 130 mill. In the insurance sector dropped the new production by 13%, however, year-on-year volume of prolonged contracts increased by more than 5%. The costs on the insurance fulfilments during the first half of the year 2013 decreased significantly year-on-year by 23,4%, whereby the number of the insurance fulfilments decreased only moderately.

The profitability and solvency of the insurance companies fundamentally did not change. The profit of the insurance sector reached EUR 158 mill., representing 16% year-on-year increase in 2013. In 2012, the profit was influenced by one-time impacts (for example: change of assessment of the property participation in subsidiaries, etc.). After the consideration of such impacts, the profit changed year-on-year only minimally. The development of the profit in the individual insurance companies was various. Two insurance companies reported a loss, but the combined loss decreased from EUR 12,5 mill. in 2012 to EUR 1 mill.

The technical result of the non-life insurance decreased by approximately a third to EUR 40,7 mill. The decrease involved particularly the decrease of the survival benefit, as well as a moderate increase of costs for insurance fulfilment and operational costs.

On the contrary, the technical result of the life insurance improved year-on-year by EUR 104 mill. The major factors included the growth of survival benefit, slow-down of the growth of costs for the insurance fulfilment and particularly the significant slow-down of the growth of unit-linked reserve by EUR 67 mill., approximately two thirds due to decrease of the profits from the investments, where the risks are borne by the client.

The technical insurance accelerated after two years in 2013 to year-on-year 5,3%. In comparison with the previous two years, the insurance grew mainly in the common life insurance, constituted by 7,2%, which occurred for the first time from 2007. The increase involved mainly new production (14 %) annual insurance (6 %), despite the decrease of the number of contracts by 4 %. This growth may correlate with the decrease of the technical interest rate from 1st January 2014 to 1,9%, which will result in higher prices of the insurance.

Conclusion

A part of this article consists of the application of the time series to the data set in order to determine a prediction of the technical insurance for the period 2013 – 2017 by usage of point and interval estimates of the division. The main task is to determine a basic tendency of their development, i.e. specification of their trend. The trend is determined by the analytical methods, i.e. by the trend functions.

The results of the statistical analyses are compared to the official published data of the National Bank of Slovakia for the first half of 2013.

Concurrently, it is estimated that the technical insurance in non-life insurance will vary around the amount of app. EUR 0,89 bil.

The comparison of the aforementioned results calculated for the entire year 2013 and the results published by the National Bank of Slovakia for the first half of 2013 shows that the difference between the estimate and the actual value represents EUR 0,07 bil, i.e. the deviation corresponds to 7%.

The technical reserves in the common life insurance, as well as in the unit-linked insurance were growing during the first half of 2013. The reserves in the non-life insurance or the placement of the technical reserves did not essentially change.

It can be concluded that the profitability of the insurance sector have not fundamentally change in the last five years and remained sufficient. The solvency of the insurance companies increased significantly due to the profits of re-evaluation of the commercial papers in the portfolio for sales. There are currently several insurance companies active on the Slovak insurance market and each year, there are various changes within their scopes. The insurance companies have to face bigger concurrence more than ever before, either from the part of the existing concurrence or from the new subjects. As a result, the insurance is dropping and the profitability is lower. The insurance companies undergo fusions and cooperate in order to create the conditions for larger business, fusion of banks and insurance companies are becoming more common.

Insurance services, i.e. the services of the insurance protection constitute a specific service on the insurance market, whereby the insurance protection develops as a need in each society due to the existence of various risks.

Each insurance company deals with a specific product portfolio and a specific clientele, which also determines its further activities.

[1] Technical reserves from self-retention, i.e. excluding the shares of a reinsurer.

[2] Placement of the resources.

[3] Insurance companies, which transformed to branches of foreign insurance companies in 2009 were not included to the total number, however, the impact of the fusion of two insurance companies in 2009 was taken into account.

Abstract

The main focus of this paper is to describe and analyze how Impact investments should affect the product portfolio of Slovak banking sector. Impact investments are intended to create positive social or environmental impact beyond financial return, and constitute a new asset class. Impact investments are typically created in private markets by providing debt or equity to mission-driven businesses. Impact investing, or we should say social investing has gained traction among a wide range of investors, including foundations, private managers, individuals, commercial banks and development finance institutions. We are assuming that investors have a wider range of expectations for impact investment financial returns what estimates a significant market opportunity for Impact investment over currently ongoing economic problems we face with great mistrust and caution in financial markets. The banking sector as such is a very important and currently is an inherent part of the economy, in almost every state. Our article analyzes Slovak banking sector which overviews the biggest opportunities in the relevant Impact investments.

Keywords: impact investing, banking sector, products, social return, social risk, Slovakia

Introduction

Slovakia as one of the youngest members of the euro area has been avoiding the problems in the banking sector, derived from global financial crisis. According to the analysis by the World Economic Forum (WEF) on the competitiveness of countries, banks in Slovakia are ranked fourth-most stable in the euro area and the fifth-most in the EU. Over the past five years, Slovak banks left over half of their profits undistributed, which provided a significant boost to their stability. In the absence of these funds, the volume of provided loans would have fallen by more than 20 percent. The Slovak banking system reports strong capitalisation metrics, with the system-wide Tier 1 capital ratio at 16%, and leverage at a moderate 7.8%. The banking system also benefits from a strong funding and liquidity profile, which will remain stable over the outlook horizon. Slovak banks will be able to fund their expanding loan books via their large and stable customer deposit base, where the total loans-to-deposit ratio remains below 100% and liquid assets accounted for a solid 30% of total assets. Moody's says that the banks' reliance on more volatile market funding will remain low, although it expects a modest increase in market funding caused by (1) the favourable interest rate environment; and (2) increased household consumption translating into a lower savings rate. Moody's has lowered its assumptions on the likelihood of government support for Slovakian banks, to moderate from high. This adjustment reflects the introduction of the Bank Recovery and Resolution Directive (BRRD) and Single Resolution Mechanism (SRM) in the European Union, which provides for burden -sharing with senior creditors. In addition, under the Loss Given Failure (LGF) framework incorporated in Moody's new bank methodology, the rating agency expects the impact on bank ratings of the new resolution framework and the reduction in our assumptions of public support to be moderated -- and in some cases fully offset -- by a decline in expected loss assumptions, particularly for Slovak banks' junior deposits given their substantial size.

Stable and efficient banking system employed in Slovakia, however, still not become a breeding ground for Impact investing which “can made in both emerging and developed markets, and target a

range of returns from below-market to above –market rates, depending upon the circumstances". (Global Impact Investing Network. "About Us" 2013, retrieved 15 December 2015).

Impact investing – an Opportunity for Improvement

Although it is possible for impact investors to achieve social impact along with market rate returns, it's not easy to do and doesn't happen nearly as often as many boosters would have you believe. There has been an increasing realization that, along with government aid and philanthropy, private companies can contribute to solving environmental and social problems. At the same time, a growing number of investors are expressing a desire to "do good while doing well". There are impact investors, who seek opportunities for financial investments that produce social or environmental benefits. However, the rapid growth of the field of impact investing has been accompanied by questions about how to assess impact, and concerns about potentially unrealistic expectations of simultaneously achieving social impact and market rate returns. Impact investors actively seek to place capital in businesses, nonprofits and funds that can harness the positive power of enterprise. Impact investments occur across asset classes and investment amounts.

Impact investing refers to investments "made into companies, organizations and funds with the intention to generate a measurable, beneficial social or environmental impact alongside a financial return (Global Impact Investing Network. "About Us " 2013, retrieved 15 December 2015). It is a form of socially responsible investing that serves as a guide for various investment strategies (Lemke and Lins, Regulation of Investment Adviser, §2:158, Thomson West 2013). Among the best-known mechanism is private equity or venture capital. Social venture capital or patient capital, impact investments are structured similarly to those in the rest of the venture capital community.

Hedge funds and private equity funds may pursue impact investing strategies (Lemke, Lins, Hoenig and Rube, Hedge Funds and Other Private Funds §6:43, Thomson West 2013).

Investors may take an active role mentoring or leading the growth of the company (Financial Advisor Magazine, Wealthy Attracted To Impact Investing. NASDAQ. Retrieved 16 December 2015), similar to the way a venture capital assists in the growth of an early-stage company.

By analyzing the inherent logics and rationalities, this framework strives to acknowledge financial returns alongside social impact while simultaneously considering implied risks. At the same time it is flexible enough to deal with various approaches to measuring social, environmental and corporate governance risk and return factors, an important necessity to serve the broad range of actors and different logics in the field. Over the last couple of year, the field of impact investments advanced in terms of market structures, involved participants and investment vehicles. Among the diverse set of stream within the social investment market, the progress achieved in impact investing received exceptional attention in practice and media. (Brandstetter, L. & Lehner, O.2014).

Private financial institutions have the increasing interest in investing into social businesses and bring the expectations of social and economic return. On the other hand, public authorities are becoming reluctant to invest in the project of innovation; they do not perform their own duties in supporting the social business, if the existing projects are financed by the philanthropic organizations or private investors. Some organizations therefore fight with the possibilities of finding the investor or gaining the necessary capital for their innovation projects and ideas. Private investors expect demonstrable social and economic return on investment, and this is the factor that forces public authorities to expect the same effect from their own investment. However, the added value is to be able to measure the social impact, because it can help to improve the products offered.

In these terms of impact investing is necessary to combine it with terms of social innovations. As part of the solution of tackling existing social problems and diminishing the negative effects of capitalism, social enterprises and social entrepreneurship emerged on the horizon of social innovation. There are many definitions of the term "social innovation" (e.g., Mulgan, 2006; This is European Social Innovation. 2010; Phills et al., 2008; Murray et al., 2009; Mulgan et al., 2007; Westley et al., 2010;

Pol et al., 2009). Some definitions are specific and exclude many examples of social innovation while others are as broad as they describe projects and organizations that are not particularly innovative, even if they are in some way social. This is partly because social innovation is a practice led field – understandings, definitions and meanings have emerged through people doing things in new ways rather than thinking about them in an academic way.

Specifically, we define social innovations as new ideas (products, services, and models) that simultaneously meet social needs (more effectively than alternatives) and create new social relationships or collaborations. In other words, they are innovations that are good both for the society and to enhance society's capacity to act. As one of the key elements of the new innovation paradigm, social innovation has become a global phenomenon, which responds to the grand challenges that our societies are facing. Social innovation research is just starting to become part of scientific discourse and the international community building is still at an early stage. With regards to their invention, development and spread, social innovations are clearly distinct from technical innovations. Due to their specific process and product dimensions, social innovations generally arise outside the realms of corporate and academic research divisions. In general, innovations are processes whereby social, public policy and economic needs are answered by new ideas, new products, services, and new business models are created. Despite of any innovations being a commendable practice, social innovations are especially relevant to the society. The global economic crisis revealed that social challenges such as demographical changes, unemployment, poverty, emigration and others are coped with in a far more complicated way than it was thought. The opportunity for social business is the possibility of the asset of private investments. (Majercakova, D., 2015).

Impact measurement as a potential for Slovak banking sector

Impact measurement is the set of practice through which an organization establishes what difference its work makes.
Social impact investments are those that intentionally target specific social objectives along with a financial return and measure the achievement of both. The financial crash of 2008 highlighted the need for a renewed effort to ensure that finance helps build a healthy society. This requires the paradigm shift in capital market thinking, from two-dimensions to three. By bringing a third dimension, impact, to the 21tst century capital market dimensions of risk and return, impact investing has the potential to transform our ability to build a better society for all. There is a growing desire to reconnect finance with meaning and purpose, to make a difference. This is leading to an increasing demand of people looking for social impact of their investments. Impact investing does not relieve governments of their responsibilities, but it can help fulfill them more effectively. By financing innovative approaches, impact investing also has the potential to help deliver services more efficiently and, in some cases tackle the underlying causes of growing demand for social services instead of just trying to cope with their consequences.

Impact investment, like any market, is a combination of demand (for capital to finance impact-driven organizations), supply (of impact capital) and intermediaries (helping to connect supply with demand). We would like to combine all of this principal components into the investment ecosystem area. Ecosystem varies according to the role of government, foundations, the private sector, individual investors, products portfolio of banking sector and social sector. From the perspective of schematic overview of the ecosystem related to the policy options available to governments are outlined areas into the Social impact investment ecosystem´s diagram (diagram 1 at next page). The principal components are:

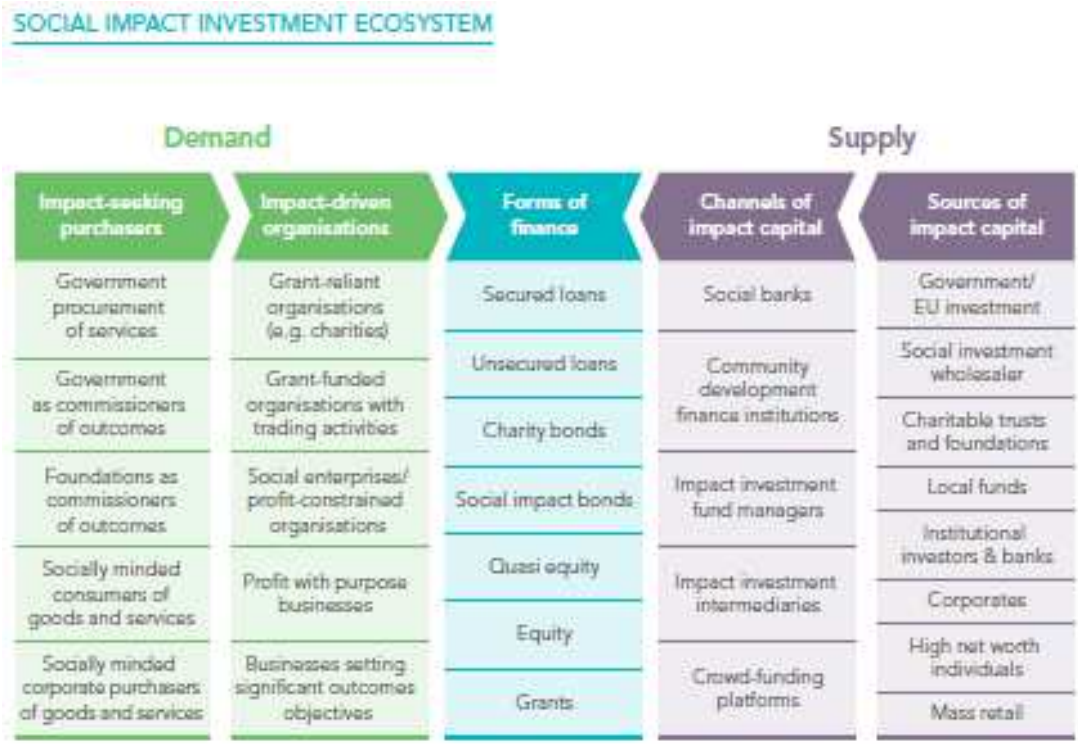
- Impact-seeking purchasers: those provide the sources of revenue that underpin investment in impact-driven organizations. Such purchasers can include governments, consumers, corporations or foundations.

- Impact-driven organizations: all types of organizations which have a long-term social mission, set outcome objectives and measure their achievement, whether they be social sector organizations or impact-driven businesses.

- Forms of finance: which are needed to address a range of different investment requirements

- Channels of impact capital: to connect investors to impact-driven organizations in situations where the sources of impact capital do not invest directly in impact-driven organizations.

- Sources of impact capital: to provide the investment flows needed.



Source: Impact investment: The invisible Heart of Markets, 2014

From the perspective of "healthy economy" and stable Slovak banks assets quality with the non-performing loans (NPL) ratio rising over 12-18 months outlook horizon we should define recommendations for establishing the healthy and stronger social impact investment ecosystem which is still needed. Slovak banks will be able to fund their expanding loan books via their large and stable customer deposit base, where the total loans-to deposit ration remains below 100% and liquidity assets accounted for a solid 30% of total assets. Moody´s says that the banks´ reliance on more volatile market funding will remain low, although it expects a modest increase in market funding causes by (+) the favorable interest rate environment; and (2) increased household consumption translating into a lower savings rate.

From the effective measurement perspective, which must be relevant, helpful, simple, natural, and certain, understood and accepted, transparent and well-explained and established on evidence; we define ten groups of recommendations for parts of social impact investment ecosystem in Slovakia.

(1) Set measurable impact objectives and track their achievement
(2) Investors to consider three dimensions: risk, return and impact
(3) Clarify fiduciary responsibilities of trustees: to allow trustees to consider social as well as financial return on their investments

(4) Pay-of-success commissioning: governments should consider streamlining pay-for-success arrangements such as social impact bonds and adapting national ecosystem to support impact investments
(5) Consider setting up an impact investment wholesaler funded with unclaimed assets to drive development of the impact investment sector
(6) Boost social sector organizational capacity: governments and foundations to consider establishing capacity-building grants programs
(7) Give profit-with-purpose businesses the ability to lock-in mission: governments to provide appropriate legal forms or provisions for entrepreneurs and investors who wish to secure social mission into the future
(8) Support impact investment's role in international development: governments to consider providing their development finance institutions with flexibility to increase impact investments efforts. Explore creation of an Impact Finance Facility to help attract early-stage capital, and a Development Impact Bond Social Outcomes Fund to pay for successful development impact bonds.
(9) Define the systematic measurement and development for understanding different changes and values the things that matter to stakeholders
(10) Be transparent and verify the results based on good research principles.

For this recommendations must be clear defined ecosystem with their weaknesses and strengthens. From the perspective of this measurements method we should conclude, that the weaknesses of the Slovak impact investments ecosystem are:

- misunderstandings of concept of impact investing;
- close "typical" bank system not open for social investments;
- corruption;
- no tax exemptions or privileges;
- absent specified subsidies;
- non-existing crowdfunding system;
- instability of social system;
- growing poverty;
- lack of knowledge and experiences in the non-typical investments.

On the other hand, strengthens should be relevant in the perspective of measurement method as a:

- crossroads of the private, public and third sector;
- concept of impact "social" investing is still in process of development and research;
- community participation on social life of society;
- recalls for the necessity of social enterprises;
- active third sector;
- active policy of employment on the local and governmental level.

Conclusion

All innovations are socially relevant, both those with objectives and rationality criteria to change economic parameters and those with social intensions and effects in the field of social practices. However, this also implies that, irrespective of what kind of innovation is to be developed, realized or examined, the meanings and effects of innovations do not remain restricted to the respectively evident functional system: technological and economic innovations affect or change not only the functional system of the economy, but also the other major functional systems as politics, law and culture.

Impact investment is about investing into people. It means policies designed to strengthen human skills and capacities and support them to participate fully in employment and social life. The biggest opportunity for social investing seeks to strengthen peoples' current and future capacities and improve their opportunities to participate in society and the labour market, and, of course, calls for investing into children and youth to increase their opportunities in life. Each of this opportunity for social investing needs at first changing of society in the meaning of social innovations and providing

social services. They may actively seek out investments – such as community development loan funds – that are likely to provide important societal or environmental benefits.

Slovak banking sector has a big potential together with strong economy for establishing the effective social impact investment ecosystem. Quality of life will be growing and also from the perspective of open space in the investments opportunities should increase level of well -being in the country.

"*As investors add the third dimension of impact to risk and financial return in their decision making, we expect there to be a considerable pool of capital looking for opportunities to invest in achieving measurable social impact*." (Impact investment: The invisible heart of markets, 2014)

Analysis of Unexpected Recovery Factors and Their Impact on IT Business Continuity Timeframes

Athanasios Podaras, Technical University of Liberec, Faculty of Economics, Department of Informatics Liberec, Czech Republic, athanasios.podaras@tul.cz

Abstract

The current paper focuses on the analysis of multiple unforeseen factors that should be taken into consideration during the formulation of the IT Business Continuity testing policy in an enterprise. The prerequisite for a successful strategy towards the avoidance of the unexpected interruption of either one or multiple computer based business functions, is the often execution of recovery exercises. During testing, however, the more emphasis is given to probable Unexpected Recovery Factors that can delay the recovery time effort of a given business function, the more organized and prepared the personnel will be in order to react immediately and recover on time all the critical business functions whose interruption may negatively influence the organization in a real emergency event.

Keywords: Business Continuity Plan, Recovery Exercises, Unexpected Recovery Factors, Unexpected Recovery Index

Introduction

The modern era is characterized by various crises which have either mild or severe impact on the operation of enterprises. In his article Skrbek (2011) generally mentions that 21st century civilization has been increasingly exposed to various crises: natural events, operational breakdowns and terrorism. Modern enterprise information systems are highly affected by such crisis events. Multiple authors refer to the parallel emergence of new enterprise operational threats due to computer based everyday business tasks. Boin et al (2005), underline that the "Information Age" has not only brought international terrorism, but also an increased awareness of new types of contingencies - breakdown of information and communication systems, energy black-outs, the emergence of natural threats, bio-nuclear terrorism, etc. Additionally, Mitroff and Anagnos (2001), among 10 different major types of crisis, highlight the importance and the presence of the informational types (loss of proprietary information). The main advantage provided by applied ICT against such threats, as it is claimed by Chroust and Finlayson (2011), is the possibility of improving prevention and recovery in many different ways.

Effective Business Continuity Planning (BCP), as part of the Business Continuity Management (BCM) process, significantly helps towards the solution to the above stated enterprise problems. Antlova et al. (2011) underline that BCM is considered to be one of the key Areas of ICT Competencies. The key element to a successful and effective Business Continuity Plan, according to the British Standards Institution (BSI) (2012), is the periodic execution of disaster recovery exercises. Furthermore, the National Institute of Standards and Technology (NIST) (2010), mentions that a Business Continuity Plan (BCP) focuses on sustaining an organization's mission/business processes during and after a disruption. However, efficient and beneficial recovery exercises should be based on crisis scenarios that may harden the timely IT business process restoration within the Rational Time Objective (RTO) or the Maximum Acceptable Outage (MAO), and augment the possibility of recovery time deviation from these defined timeframes. Throughout the present work six Unexpected Recovery Factors are illustrated and analyzed as different multiple unplanned situations which can negatively influence and significantly delay the recovery procedure of critical business functions. The final step of the current contribution includes the approximate calculation of a function's recovery

time deviation from the defined by BSI (2012) RTO/MAO timeframes. The estimation approach is based on the Composite Risk Index theory of Risk Management and is entitled *Unexpected Recovery Index*.

Problem Definition

The author of the present article aims to provide justified answers to the following questions:

1. Are there any factors which should be considered throughout business continuity exercises that are practically underestimated or ignored by business continuity experts and ICT managers?
2. How can these factors be assessed and which is their precise impact on the recovery time of a given business function?
3. Is there any tool for the proactive estimation of the resumption timeframes for a specific function and the involved ICT applications, when the aforementioned factors influence the recovery procedure? Which is the approximate time deviation from the RTO and MAO values?

According to Engemann and Henderson (2012), testing and exercising assesses the viability of a business continuity plan. However, it has been noticed that practically, business continuity exercises are not sufficiently executed. Miller and Engemann (2012) underline that BCP plan maintenance and testing is a critical step but may receive insufficient resources or lack of organizational support. At the same time, multiple factors that may influence the recovery procedure are not taken into consideration during business continuity exercises. In his dissertation, Tjoa (2012) mentions that besides the incidents presented by the media, a huge variety of less spectacular threats exists that endangers the existence of companies. Examples of such threats are loss of key staff, loss of knowledge, disgruntled employees, insider threats or software failure.

The author of the current paper identifies six serious Unexpected Recovery Factors that can negatively influence and significantly delay the recovery process of the core enterprise business functions. These factors should be always considered throughout the formulation of a business continuity policy. Their classification is inspired from the recovery exercise policy recommended by the BSI (2012). The Unexpected Recovery Factors (URF) concept was initially introduced by Podaras and Zizka (2013) as part of the Business Continuity Testing Points (BCTP) approach to the estimation of criticality of multiple ICT operations and their corresponding software applications. The same concept was also utilized by Podaras (2015) in a more general and improved expression of the approach, entitled Business Continuity Points, where an unlimited number of unexpected factors is considered. The latter method was highly influenced by the Business Continuity Exercises checklist document as it is proposed by the Information and Technology Services (ITS) – University of Michigan (2014). Both methods are based on the Karner's (1993) Use Case Points approach which is utilized for software development complexity estimation.

The proactive and approximate calculation of the recovery time deviation from the expected RTO/MAO resumption timeframes, is also a crucial issue of the current contribution. A method entitled Unexpected Recovery Index, which is based on the Composite Risk Index theory of risk assessment, is utilized for implementing this part. Miller and Engemann (2012) support that risk management in BCM provides an analytical foundation for decision making. The same authors highlight that because BCM deals with events that are improbable, analyzing risks is challenging.

Analysis of the Unexpected Recovery Factors

Weather Conditions: Unexpected extreme weather conditions during a sudden system outage may prevent the IT special team from reaching the recovery site. Such a scenario is crucial for business continuity exercises. A list of involved types of weather conditions with their corresponding assessment values as well as their impact on the recovery time of a given business function, is depicted at Table 1.

Table 1: List of weather conditions and their corresponding assessment values

Impact/Severity Level	Weather Condition Type	Assessment Value
Very High	Extreme Weather Conditions (i.e. heavy snowfall)	4
High	Difficult Weather Conditions (i.e. rainfall causing flood)	3
Middle	Not Usual Weather Conditions (i.e. foggy, windy including mild problems)	2
Low	Normal Weather Conditions (i.e. cloudy, soft rainfall)	1

Disaster Types: Rodriguez et al (2007) mention that a disaster is an event concentrated in time and space, in which a society or one of its subdivisions undergoes physical harm, and social disruption, such that all or some essential functions of the society or subdivisions are impaired. Additionally, Lindel (2011) states that a disaster recovery begins with stabilization of an incident and ends when a community has re-established normal, social, economic and political routines. The size and the extent of a damage and an information system interruption is highly dependent on the type of the disaster or the emergency incident. Table 2 includes the classification of various disaster incidents, based on their severity level. Each disaster type is assigned a corresponding assessment value.

Table 2: List of disaster types and their corresponding assessment values

Impact/Severity Level	Disaster Type	Assessment Value
Very High	Extreme Situation (i.e. destroyed building by earthquake)	4
High	Difficult Situation (i.e. server failure due to fire or flood)	3
Middle	Not Usual Situation (i.e. hackers' attack, network failure)	2
Low	Normal Situation (i.e. electricity failure)	1

Timely Disaster Declaration: The timely announcement of a disaster is a crucial element of an efficient business continuity plan. Bird (2007) states that BCP is likely to comprise several elements one of which is immediate reaction procedures (incident management, disaster declaration, evacuation, damage assessment and limitation). The influence level of the untimely transmitted information, is considered to be either High and is marked with 4 or Low and is marked with 1(Table 3).

Table 3: Classification of Information Distribution

Impact/Severity Level	**Information Distribution**	**Assessment Value**
Very High	Very Slow Information Distribution	4
Low	Rapid Information Distribution	1

Urban Conditions: Another important factor that has to be considered in terms of business continuity test planning, is the urban conditions. What can happen in case of heavy traffic during the day of the information system failover, or if traffic lights don't operate or if the emergency situation is announced at night or during rush hour? It is obvious that urban problems during a sudden system outage may prevent the IT special team from reaching the recovery site. A classification of urban conditions as an Unexpected Recovery Factor is depicted at Table 4.

Table 4: List of Urban Conditions and their corresponding assessment values

Impact/Severity Level	**Urban Condition**	**Assessment Value**
Very High	Extreme Situation (i.e. large area around building destroyed due to a flood)	4
High	Difficult Situation (i.e. heavy traffic because of a serious accident or traffic lights out of work)	3
Middle	Not Usual Situation (i.e. heavy rush - hour traffic)	2
Low	Normal/Convenient Situation (i.e. system failure is during night and no traffic problems exist)	1

Staff Availability: According to Engemann and Henderson (2012), teams play a significant role in Business Continuity Management. The same authors indicate that it should it kept in mind that some individuals may not be available to perform certain of their responsibilities during a crisis. The specific factor cannot be ignored when planning the exercises of crisis response, since team members might not be able to participate in the real system restoration due to various reasons such as sickness, holiday, weak or no mobile signal, pregnancy (regarding female staff) and other personal reasons. In such cases, recovery time is highly dependent on the percentage of available employers and also on the skills and responsibilities of the available staff (Table 5).

Table 5: Staff availability and its corresponding assessment values

Impact/Severity Level	Urban Condition	Assessment Value
Very High	Extreme Situation (i.e. big area around building destroyed due to a flood)	4
High	Difficult Situation (i.e. huge traffic because of serious accident or traffic lights out of order)	3
Middle	Not Usual Situation (i.e. traffic because it is rush - hour)	2
Low	Normal/Convenient Situation (i.e. system failure is during night and no traffic problems exist)	1

Network Availability: Piedad and Hawkins (2001), underline that within an unplanned network unavailability system complexity, problem severity and staff availability are the most important factors that correlate with the length of recovery time. Moreover, Philippa et al. (2011) declare that many system operators prioritize severe incidents for troubleshooting based on their impact to end – users and applications. Thus, network availability affects significantly the recovery procedure of the enterprise operations. The classification of Impact/Severity level according to the type of network failure incident with regard to its effect on end – users and applications is depicted on Table 6.

Table 6: Network availability and its corresponding assessment values

Impact/Severity Level	Urban Condition	Assessment Value
Very High	Extreme Situation	4
High	Difficult Situation	3
Middle	Not Usual Situation	2
Low	Normal/Convenient Situation	1

The Concept of Unexpected Recovery Index

The estimation of the specific index is based on the Composite Risk Index notation, which stems from the most widely accepted formula for risk quantification as it is described by Ciobanu and Mazilu (2011), which is the following:

$$RISK\ MAGNITUDE = RATE\ (or\ PROBABILITY)\ OF\ OCCURENCE\ \times\ IMPACT\ OF\ EVENT \quad (1)$$

Similarly, the *Composite Risk Index (CRI)* is calculated according to the following formula:

$$COMPOSITE\ RISK\ INDEX = IMPACT\ OF\ RISK\ EVENT\ \times\ PROBABILITY\ OF\ OCCURENCE \quad (2)$$

According to the Composite Risk Index theory, the Impact is marked on a scale from 1 to 5, where 1 is the minimum impact value and 5 is the maximum impact value. Moreover, the probability of occurrence is also marked on a 5-level scale. It is thus realized that the minimum value for CRI is 1 and the maximum value of CRI is 25.

The Unexpected Recovery Index (URI) estimation, stems from a modified by the author CRI model. Since the URI model is formulated in terms of the above analyzed six Unexpected Recovery Factors, which are included in the Business Continuity Testing Points (BCTP) methodology where the unexpected factors are classified on a 4-level scale. As a result, according to the newly introduced model, the minimum impact value of an event is 1 while the maximum impact value is 4. For the Probability of Occurrence of each unexpected factor the same scale is implemented.

Moreover, the Modifier Impact (MI) notation is introduced. The equation should calculate the sum of all the factors' impact multiplied by the probability of occurrence of each factor. Considering the Composite Risk Index methodology, the derived equation for estimating the Unexpected Recovery Index (URI) value is the following:

$$URI = MI \times P \quad (3)$$

where, MI = Modifier Impact and P = Probability of Occurrence

According to Equation (3) and the data obtained by the Table 7, the minimum and the maximum URI values regarding each factor are: $URI_{MIN} = 1$ and $URI_{MAX} = 16$.

Table 1: The 4-level scale for Impact and Probability of Occurrence of an Unexpected Recovery Factor

Probability of Occurrence of each URF / Impact of each URF	1	2	3	4
	Unexpected Recovery Index (URI) Of Each URF Modifier			
1	1	2	3	4
2	2	4	6	8
3	3	6	9	12
4	4	8	12	16

However, according to the model, the Total URI value is calculated as the sum of all the emerging URF modifiers,

$$URI = \sum_{i=1}^{6} (MI \times P) \quad (4)$$

where, MI = Modifier Impact and P = Probability of Occurrence

According to the new model there are 2 basic scenarios regarding the emergence of unexpected factors. The Best Case Scenario considers the emergence of only one (1) URF (modifier) and in its mildest form. In this case, the Minimum Total URI value is 1. On the other hand, according to the Worst Case Scenario, all possible URF should emerge during an unexpected outage and in their most severe form. In this circumstance, the Maximum Total URI value is 96.The following section delineates the derivation of the complete URI equation, which will be utilized to estimate both Recovery Time Deviation (RTD) caused by the modifiers or Unexpected Recovery Factors as well as the Total Recovery Time Effort (TRTE).

Derivation of the Complete URI Formula and Estimation of the Total Recovery Time Effort Based on the URI Value

Before estimating Time Deviation from the initially defined resumption timeframes (RTO, MAO), it is accepted that the maximum time deviation, in the worst case scenario (maximum probability of occurrence of all URFs in their most severe form), should be the following:

$$RTD_{MAX} = RTE \quad (5)$$

where, RTD = Recovery Time Deviation, and RTE = Recovery Time Effort initially planned by the Business Continuity managers. A different expression of the relation between RTD value and RTE can be the following:

$$TRTE = RTE + RTD \quad (6)$$

where, TRTE = Total Recovery Time Effort and RTD = Recovery Time Deviation.

From Equations (5) and (6) we derive the following formula:

$$TRTE_{MAX} = 2 \times RTE \quad (7)$$

The calculation of the RTD value should be based on the following formula:

$$RTD = RTE \times \frac{URI}{100} \quad (8)$$

According to Equation (8), the estimated time required to recover an IT business function and its peripheral applications, might be influenced by the presence of various unexpected factors, in a percentage that can be quantified by URI. The most secure expression of the model is the derivation of the URI initial formula according to the scenario of the most stressful crisis event, where RTD = RTE. In such a case URI =100. As a result, the following Equations should be derived:

$$URI = \sum_{i=1}^{6}(MI \times P) = \sum_{i=1}^{6}(\frac{100}{100} \times MI \times P) \cong \sum_{i=1}^{6}(\frac{100}{96} \times MI \times P) =$$

$$= \sum_{i=1}^{6}(1{,}04 \times MI \times P) \quad (9)$$

$$RTD = RTE \times \frac{\sum_{i=1}^{6}(1{,}04 \times MI \times P)}{100} \quad (10)$$

and finally, $$TRTE = RTE\ (1 + \frac{\sum_{i=1}^{6}(1{,}04 \times MI \times P)}{100}) \quad (11)$$

Equations (10) and (11) provide the Recovery Time Deviation from the initial RTO and MAO values and the Total Recovery Time Effort respectively, based on the emergence of severe URFs in an IT System outage. The model's maximum accepted time deviation will result to business function restoration within twice as much time as initially planned.

Conclusion – Future Work

The present study is part of an ongoing research, which aims to the construction of a precise model for planning efficient business continuity exercises regarding IT business functions or systems, based on scenarios of hard and mild crisis events. The target task of the current paper is the delineation of six Unexpected Recovery Factors (URF), which can significantly delay the recovery process of critical business functions. In these cases, the URFs act as modifiers since they will change the estimated IT recovery time, as it is expressed by the Maximum Acceptable Outage (MAO) and Rational Time Objective (RTO) timeframes. The second task achieved through the present work is the calculation of the Time Deviation from the initial recovery plan and the Total Recovery Time Effort required to restore the process under the assumption of the emergence of an unexpected recovery factor. The calculation is based on the Composite Risk Index theory of Risk Management. The maximum accepted time deviation is defined by the author as the recovery time of a business

function within double time from the initially defined value. Future research results will comprise of more detailed analysis of each factor, and the exact definition of multiple crisis event types and their corresponding disaster impact level and assessment values. Future work will also entail the application of the model to real public and private organizations. The idea is to compare existing recovery timeframes indicated by business continuity experts with the recovery time effort estimated by the delineated scientific contribution.

Abstract

The ability to innovate is generally assumed as a critical success factor for growth and future performance of companies. Drawing on data from both the *EU Industrial R&D Investment Scoreboard* and PATSTAT, the purpose of this study is to provide evidence of the impact of the investment in R&D on companies' innovation and financial performances. A three-stage model is tested with R&D effort influencing innovation performances, which, in turn, affect financial performances. Regression analysis confirmed the proposed model. The work offers clear implications for managers who should put additional emphasis on innovation, as it is an important element for achieving improved overall firm performance and sustainable competitive power.

Keywords: Innovation; R&D investments; patent counts; performances.

Introduction

Innovation is widely regarded as one of the most important sources of sustainable competitive advantage in an increasingly changing environment. Actually, innovation leads to product and process improvements, makes continuous advances helping firms to survive, allows companies to grow more quickly, be more efficient, and ultimately be more profitable than non-innovators (Atalay et al., 2013; Cheng et al., 2010; Edison et al., 2013).

The impact of innovation activities on firm performances has been a matter of significant interest to economists and policy makers for decades (Hashi and Stojčić, 2013). A large number of empirical contributions has confirmed that there is a positive relationship between innovation and company performance (Kafetzopoulos and Psomas, 2015). Just to name a few:

- Cainelli et al. (2004) show that innovating firms in the service sector out-perform non-innovating companies in terms of productivity levels and economic growth;
- Evangelista and Vezzani (2010) prove that the joint introduction of product, process and organizational innovations gives to manufacturing and service firms a clear competitive advantage vis à vis both non-innovating companies and firms with a narrow approach to innovation;
- Li et al. (2010) uncover a positive effect of two types of innovation activities - i.e. exploratory and exploitative - on performance;
- Gunday et al. (2011) state that innovation has a positive impact on firm's innovative, production, market and financial performances;
- Price et al. (2013) find a positive relationship between innovativeness and family firm performance.

The success of innovation inputs in the achievement of innovation outputs has been frequently analyzed within the framework of a knowledge production function, where the output is measured by indicators of innovation results (e.g., patent counts) and the input is principally R&D capital or R&D expenditures (Beneito, 2006).

The aim of this paper is to provide empirical evidence on the relation among in-house R&D, innovation performances and financial performances of companies (Figure 1). Several studies in literature investigate such issue employing R&D investment, patent filings and sales as framework's variables (e.g. Artz et al., 2010; Chakrabati, 1991; Hsu et al., 2013).

Figure 1. The theoretical framework

The work is based on the innovative behavior of 118 worldwide top R&D spending firms in three industries - automobile and parts, bio-pharmaceutical and technology hardware & equipment - from 2003 to 2014.
The paper proceeds as follows: first, the methodology is presented; then, results are discussed; finally, conclusions are outlined.

Methodology

Data were first collected from *The EU Industrial R&D Investment Scoreboard*, which annually reports the worldwide top R&D spending companies for the previous year: twelve scoreboards were available on the internet, from 2004 to 2015, and referring to the period 2003-2014. During this period, three sectors were constantly top spenders - automobile & parts, bio-pharmaceutical and technology hardware & equipment - thus we confined the analysis to them. Since we were interested in analyzing long-run innovative behaviors, we limited the analysis to only those companies that were constantly present in the scoreboards. Yet, the scoreboard only reports data such as R&D investment, sales, number of employees, but totally lacks as to the patents held by companies. For this reason, in order to obtain such data, PATSTAT database was used and some firms were discarded because they did not filled any patent application during the investigated period. The final sample consists of 118 companies, as described in Table 1.

Table 1. Sample description

Segment	No. of companies
Automobile	12
Parts	13
Biotechnology	7
Pharmaceutical	29
Computer HW and office equipment	10
Semiconductors	36
Telecommunications equipment	11
Total	118

For each of the three constructs of the framework, four possible metrics were considered: an absolute indicator, a relative measure and the growth of both (Table 2).

Table 2. The variables

R&D effort	Innovation performances	Financial performances
1. R&D investment [M€]	5. No. of patents	9. Sales [M€]
2. R&D intensity [%]	6. Patents per employee (*1000)	10. Sales per employee [k€]
3. R&D investment growth [%]	7. Patents growth [%]	11. Sales growth [%]
4. R&D intensity growth [%]	8. Patents per employee growth [%]	12. Sales per employee growth [%]

Results

Table 3 shows the results of one-way ANOVA as to the mean values of the investigated variables over the twelve-year period using segment as a discriminating factor. Statistically significant differences are found for almost all the variables. On average, Automobiles companies have higher values of R&D investment and sales and they are the only firms registering an average growth in the number of patents per employee during the period, but the highest number of patents is found for Parts companies, whereas the highest patents to employee ratio is achieved by Semiconductors firms.

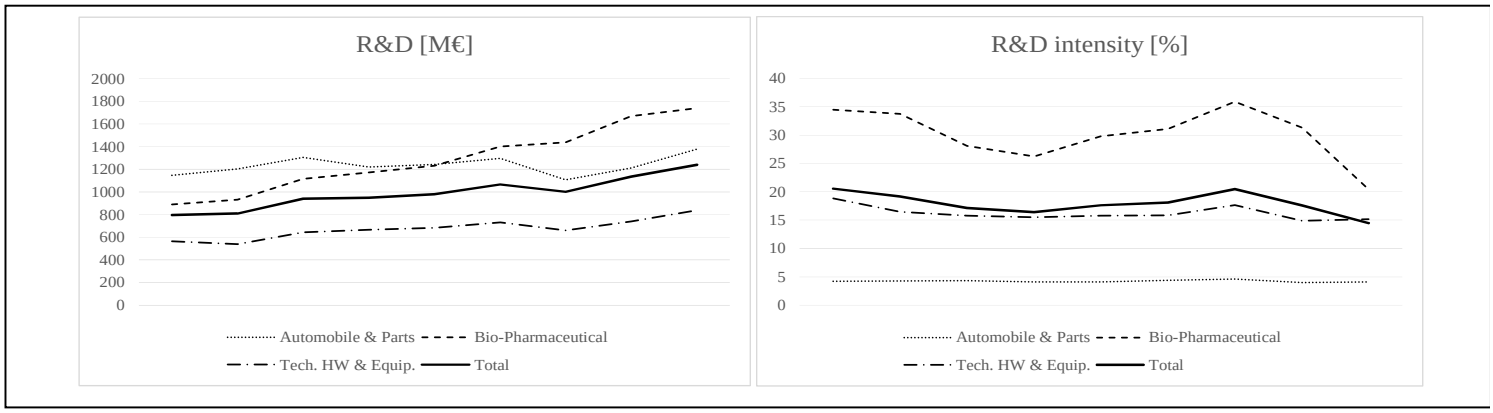

Figure 2. Trends of the investigated variables

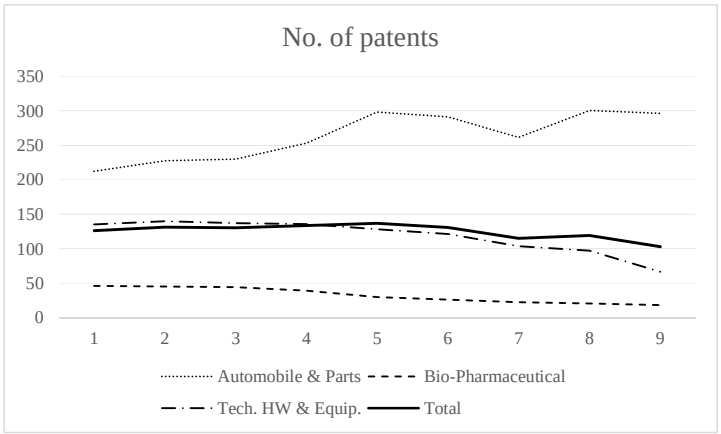

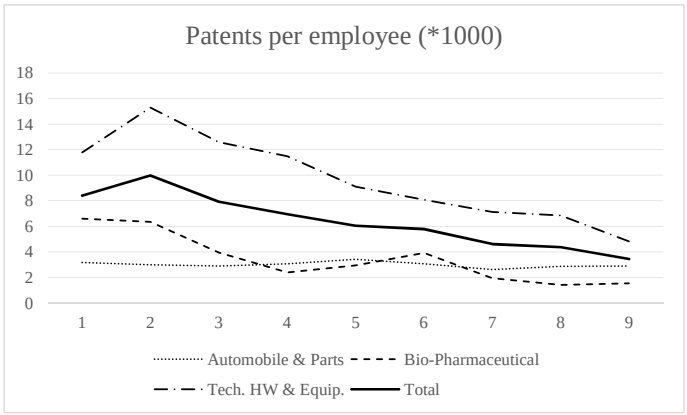

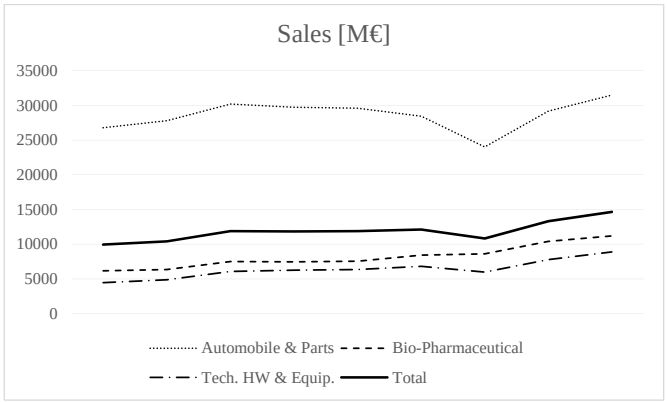

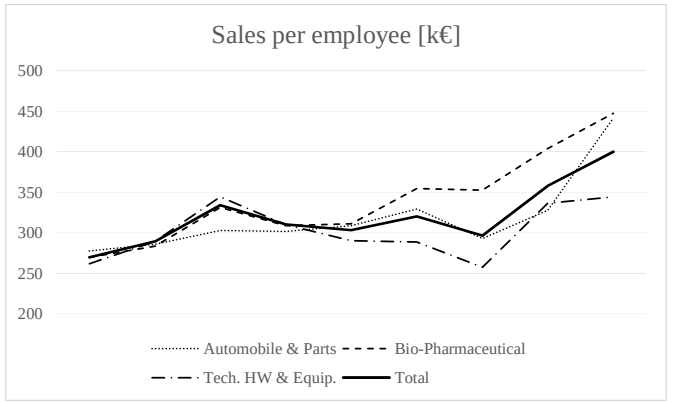

Figure 2. (continue) Trends of the investigated variables

Biotech companies show the highest values of R&D intensity and of R&D investment growth during the twelve years; furthermore, even if the absolute value of sales is small, if compared to the other segments, they have the highest value of sales to employee ratio and show the highest rates of sales growth. Looking at the sample as a whole, all variables show a generally increasing trend during the period, except the no. of patents, the patents per employee and the R&D intensity (see also Figure 2).

For each year of the period under investigation, correlation analyses were performed: the Shapiro-Wilk test of normality was employed and, since the data do not show a normal distribution, Spearman correlation was used. Actually, during the investigated period, the relationships between the different variables were quite stable, therefore, for brevity's sake, only correlations between the mean values are reported (Table 4).

Table 4. Spearman's correlation

12.	-.056	.334(**)	.070	-.392(**)	-.193(*)	.010	-.146	-.062	-.179	.172	.249(**)	1

(**) the correlation is significant at .01 level, (*) the correlation is significant at .05 level

All the three absolute indicators are positively correlated each other, suggesting that when innovation input (i.e. R&D investment) is high in entity, also its outputs (patents and sales) are high. Positive correlation is also observed between two of the three relative metrics - R&D intensity and patents per employee - confirming the input-output relationship. R&D intensity is also positively related to R&D, sales and sales per employee growth, denoting that the companies that invested greater portions of their sales in R&D had higher growth during the analyzed period. Yet, R&D intensity is negatively linked to the number of patents and to the sales, suggesting that the companies intensively investing in R&D are quite small.

R&D growth during the investigated period is associated with patents growth, suggesting that additional efforts in R&D are capable of producing an increase in the number of patents. Yet, R&D growth is negatively related to the absolute values of both patents and sales, pointing out that such increase is mainly observed in small companies. While the total number of patents is positively associated to sales, the patent to employee ratio shows a negative correlation, denoting that the smallest companies have a higher efficiency as to the patenting process.

In order to deepen the understanding of the relationships among the variables under investigation, regression analyses were performed. The regressions were performed after a cross-section perspective, using the data of R&D investment from 2003 to 2010, number of patents from 2004 to 2011 and sales

from 2007 to 2014. Thus, for each company we had eight observations, for a total number of 944 statistical units. Furthermore, three dummy variables (AU-PA, BIO-PH, THE) defining the three sectors were used as controls.

Several regression models were tested in order to find out:

1. which of the four variables describing each construct provides the best fit;
2. which time-lag should be used between independent and dependent variables;
3. which is the shape of the relationships.

The best fit was obtained when (Table 5):

1. the three absolute metrics are used, i.e. R&D investment, number of patents and sales;
2. the time-lag between R&D and patents is one year, the delay between patents and sales is three years;
3. a cubic model is used.

Some considerations can be made as to the time-lags. In the relationships between R&D investment and patents only one year was found as delay: this is certainly due to the prevalence, within our sample, of companies operating in the technology hardware & equipment industry. As a matter of fact, in this sector the new product development process is fast due to the high obsolescence of technology. Indeed, the date registered by PATSTAT is the application date, i.e. the date in which the applicant requests for the patent, which is reasonably near to the moment in which the innovation effort has been made. This also explains the longer time-lapse obtained between patent and sales, since from the application to the approval of a patent at least 18 months are spent.

Another observation can be pointed out as to the shape of the two curves (Figures 3 and 4).

The number of patents exhibits an inverted-U shape but, in the range of observed values for R&D investment, the decreasing branch is only hinted. The trend suggests a decreasing productivity of R&D efforts: for small values of investments, the growth of R&D implies an increase in the number of patents, but such increases are smaller and smaller as investments grow, until a saturation is reached. This can be explained because, even if R&D investments are necessary to generate new patents, over certain thresholds they may be no more sufficient, and other issues have to be taken into account. As to sales, they show a generally increasing trend with the number of patents, with an intermediate range of values where a quite flat tendency is observed. The finding proves that patents are particularly able to generate sales either for small companies - which can sometimes rely only on one proprietary technology for their competitive power - or for very large ones, where technology and innovation management processes are well structured and organized towards the maximization of results.

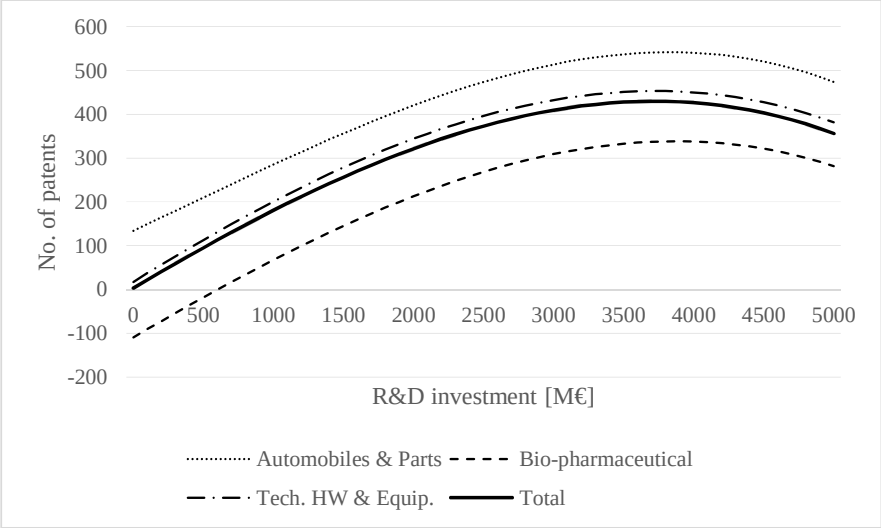

Figure 3. Regression curve of number of patents as a function of R&D investment (cubic model)

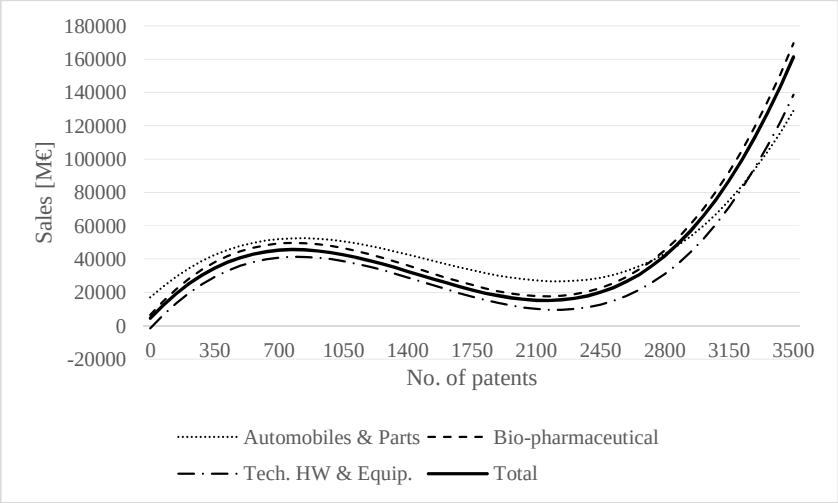

Figure 4. Regression curve of sales as a function of number of patents (cubic model)

Finally, the relation between R&D investment and no. of patents is positively influenced by automobile & parts and technology hardware & equipment industries, negatively by the bio-pharmaceutical sector. On the contrary, the linkage between no. of patents and sales is positively mediated by automobile & parts and bio-pharmaceutical sectors, negatively by the technology hardware & equipment industry. Therefore, carmakers and part producers are more able to transform their R&D investments in patents and their patents in salable products.

Conclusions

The impact of innovation on performances has been a matter of significant interest to economists and policy makers for decades. This paper aims at entering the debate by giving additional evidence of the impact of R&D investment on innovation and financial performances of companies.
A three-stage model was proposed, where R&D effort influences the innovation performances, which, in turn, affect financial results. The model was tested on a sample of 118 worldwide top R&D spending firms in three industries - automobile and parts, bio-pharmaceutical and technology hardware & equipment - by analyzing their R&D investments, number of patents and sales over a twelve-year period from 2003 to 2014. Empirical evidences confirmed the validity of the model (Figure 5).

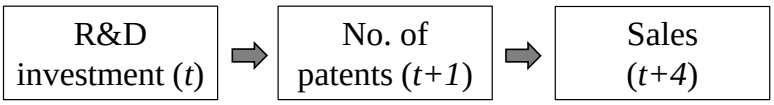

Figure 5. The empirical model

The paper provides clear implications for managers who should put additional emphasis on innovation, as it is an important element for reaching improved overall firm performance and sustainable competitive power. Yet, the work has some limitations, mostly linked to the fact that it is a first attempt to understand a very complex phenomenon: trying to synthesize innovation by the use of only three indicators can be an excessive simplification. Furthermore, the analysis is limited to three sectors, all characterized by high levels of R&D investments; therefore, the results are not generalizable to low-tech industries.

Future development of the work will include the investigation of the open innovation models (Michelino et al., 2015a) as well as of the technological strategies companies implement (Michelino et al., 2015b) and will be addressed to the analysis of more industries, in order to enhance generalizability.

Mariana Coanca, Romanian-American University, Bucharest, Romania, coancamaria@yahoo.com

Abstract

The management of agriculture is an area which lately has depended heavily on the information provided by remote sensing. This information is used to monitor agricultural plantations, soil water content, or their evolution in time and space. In conjunction with the rapid advances in computing and position locating technologies, remote sensing platforms are now capable of providing detailed spatial and temporal information on plant response to the local environment that is needed for the site specific agricultural management approaches. For this study, the Danube Delta was chosen, as it is a unique place with a great agricultural potential. The images that were used in this article were offered for free by the Landsat 8 satellite and were combined in ArcMAp10.1.

Keywords: agriculture, Danube, Landsat, land cover

Introduction

The territory of the Danube Delta reserve covers an area of about 580,000 hectares. This area comprises the Delta itself, the complex lake Somova – Parcheş, the lake Plover - Murighiol and the marine area between the coast and 20 m isobaths.

The geographic position of the reserve is defined by the following geographic coordinates: $28^0 10' 50''$ (Cotul Pisicii), $29^0 42' 45'$ (Sulina), $45^0 27'$ eastern longitude, (Chilia, km 43) and $44^0 20' 40''$ (Cap Midia) in the north.

From the total reserve, 312 440 hectares are represented by the natural ecosystems of aquatic and terrestrial areas included in the list of World Heritage and those for ecological restoration areas that represent the public land of national interest. The remaining areas include dammed areas for fishery, agriculture and forestry (80.000 ha) and areas that comprise private or public land of local interest within towns or municipalities (29.000 hectares), and a marine buffer zone of about 103.000 hectares. The Delta is situated on the territories of three administrative districts:

Tulcea 48, 9 %
Constanța 2, 89%
Galați 0,098%

The Tulcea County is located in the western part of Romania, at the influx of the Danube into the Black Sea. The territory is bordered in north by the Galați County, in the west by the Brăila County, in the south by the state border between Romania and Ukraine. The Tulcea County has an area of 8497, 75 km and occupies 3.5% of Romania, being the 4th largest in the country.

The land areas of the Danube Delta do not include the marine buffer zone, which has an area of 1030 sq. km and the marine economic zone which has an area of 374, 92 sq. km.

The agricultural lands occupy an area representing 11.6% of the Delta and are mainly concentrated in the proportion of approx. 68% in the river delta, which is more developed in terms of morphologically and pedologically.

Out of the 61220 hectares of agricultural land, over 54% are in agricultural areas which are dammed and drained, and the remaining ones are on the Chilia field, the marine levee deposits, the shore levees of the main arms and the river-marine levees. The agricultural land is exploited, the highest share being represented by the arable land (67.61%), followed by the natural grasslands (32.04%). The vineyards and orchards occupy an insignificant percent (0.34%) and they are usually located inside villages on private lots of residents.

The agricultural land located on marine, deltaic plain levees of shore which are under a free regime of flooding are occupied by pastures and small arable land which is traditionally exploited by the local population, most of them being breeders and small producers of cereals, vegetables and fodder.

Also, an important role in the Danube Delta is played by natural grasslands which occupy an area of 22.490 hectares, the great majority of areas being represented by communal fishponds which occupy an area of 2.160 hectares.

In terms of genetics, the Danube Delta is the youngest territory of Romania. The soils are young, many are still developing, and the process of pedogenesis is at the beginning. The soils of the Delta formed and evolved under circumstances of cyclical flooding; they are defined by hydromorphy, generally prevailing the gley soils.

The Delta climate falls within the temperate continental climate with pontic influences, thereby it singularizes itself as a complex topoclimate. This complex topoclimate is set at the geographic position (45 ° latitude) and reduced altitude (0-12 m), comprising large areas of water and pond vegetation, sand banks and marine levees consisting of sands with varying degrees of coverage, scrub and grass vegetation, and having a wide opening to the Black Sea.

The general circulation of the air is zone-specific, western-type the most part of the year, which causes the advection of moist sea air. The great coolings during winter are due to the continental air invasions of the southern periphery of the eastern European anticyclone or due to the Arctic advection in the long-wave through movement. The Mediterranean cyclones entering the Black Sea - have a particular evolution, most often retrograde - determines abundant rainfalls and strong winds from the east-northeast.
Thus, the thermal condition (air temperature) is moderate with a slight increase from west to east.

Materials and Methods

The satellite remote sensing currently applies to various fields, including monitoring of different areas of land. This led to the understanding of natural phenomena and processes taking place on our planet.

Rogan J and Chen DongMei (2004) mentioned that the myriad of satellite systems which are equipped with various sensors allows the takeover of records with different spatial, spectral, radiometric and temporal resolutions, thus dictating the type of the application to be used.

In the case of optical sensors, the bands in which images are taken and in the case of radar sensors, the angle of incidence and tape are highly important as they set out the application.

The vegetation covers a large proportion of the study area. In order to achieve the vegetation dynamics analysis or evaluation of its state, remote sensing can be used. According to Campbell J. B. (1987), the main advantage is the ability of vegetation to reflect incident electromagnetic radiation, thus providing qualitative and quantitative information about the status.

For the analysis of the study area, images offered for free by the satellite Landsat 8 were used. These images are for a selected surface of the Danube Delta and were downloaded from the portal: http://glcf.umd.edu/. Spatial resolution is: 15 meters/30 meters/100 meters (panchromatic/multispectral/thermal).

In the paper by Roy D.P. et al. (2014), it is said that changes involved in using the land cover are an important part of global changes affecting the environment. These changes are altering (increasing or decreasing) the density and composition of details of land and the conditions, all being registered by the satellite image.

Landsat 8 includes additional bands, as the combination used to create RGB (Red, Green, Blue) composites differ from Landsat 7.

Landsat 8 is used for agriculture monitoring and depends on different ranges of frequencies along the electromagnetic spectrum – because a color is not necessary visible to the human eye. Each range is called a band, and Landsat 8 has 11 bands (Short, N., 1982).

A widely used method to detect changes is the combination of spectral bands resulted in imagery that reflect colors depending on the order of bands used and their spectral response.

Band 1 senses vivid blue and violet. The blue light is hard to collect from space because it is easily scattered by tiny bits of dust and water in the air, and even by air molecules.

Bands 2, 3 and 4 are visible blue, green and red. Bands 5 measure the near infrared. This part of spectrum is especially important for monitoring agriculture land as the healthy plants reflect it. The water in their leaves scatters the wavelengths back into the sky.

By comparing it with other bands, indexes like NDVI are determined, which allow us to measure the plant health more precisely than in situations when we usually looked at visible greenness (Small C. 2002).

Bands 6 and 7 cover different slices of shortwave infrared or SWIR. They are particularly useful for distinguishing wet earth from dry earth, and for geology: i.e. rocks and soils that look similar in other bands often have/show a strong contrast in SWIR.

Band 8 is the panchromatic band. It looks like a black and white film: instead of collecting visible colors separately, it combines them into one channel.

Results and Discussion

For the Landsat 8 satellite, the most used combinations of bands to interpret vegetation characteristics are the following (GDSC, 2014):

1. Bands 123 (band 1 coastal/aerosol, band 2 in blue and band 3 in green). This combination image shows how reality is perceived. Band 3 (green) generally permits the differentiation of the main types of vegetation: forests and meadows (Figure 1).

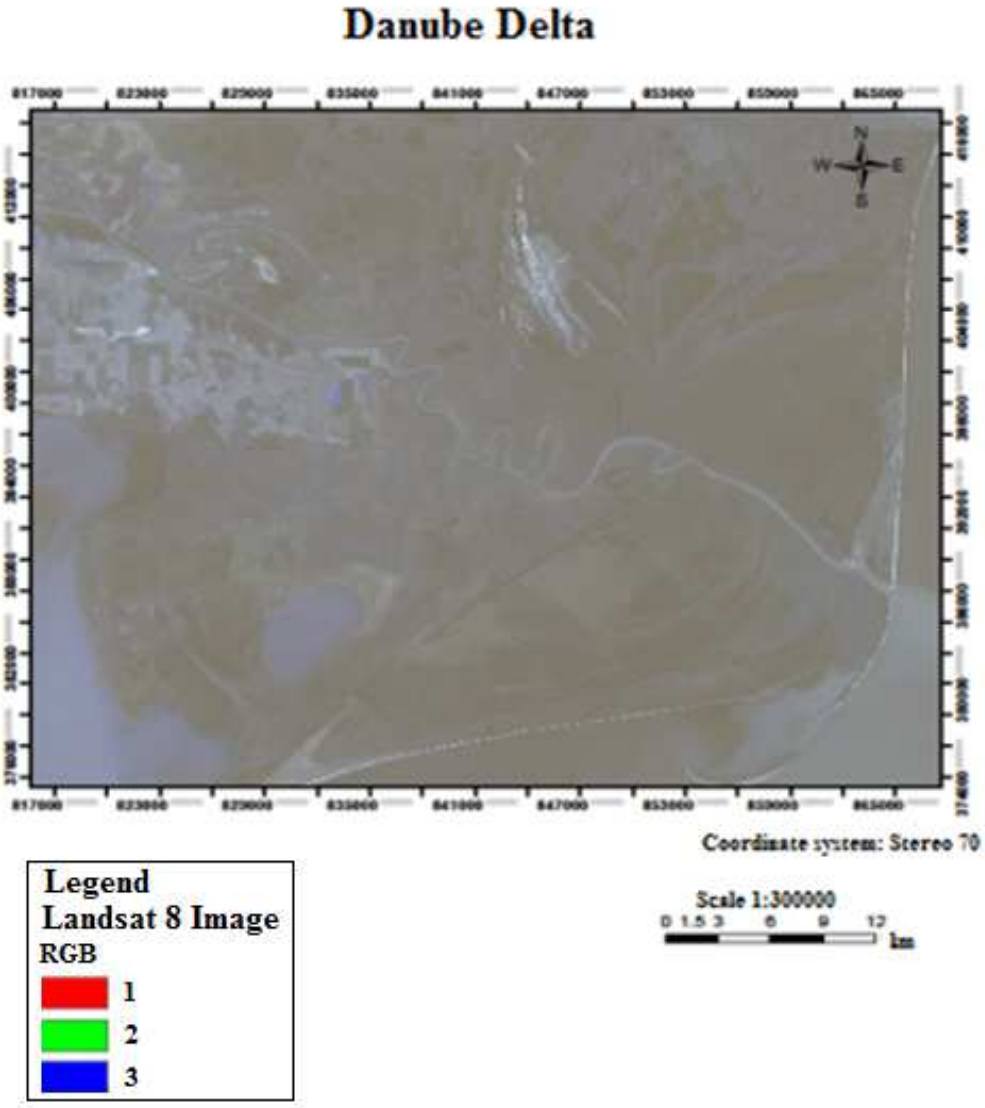

Figure 1: Landsat 8 – bands 123

2. Bands 234 (band 2 in blue, band 3 in green and band 4 in red). Band 4 allows the differentiation of vegetation types through the image analysis where lighter tones represent a stronger spectral response (Figure2) (Lillesand, T.M., Kiefer, R.W., 1994). In this image, it can be observed that the vegetation signal represented by the green band (band 3) is much lower than the vegetation signal represented by band 5 (NIR).

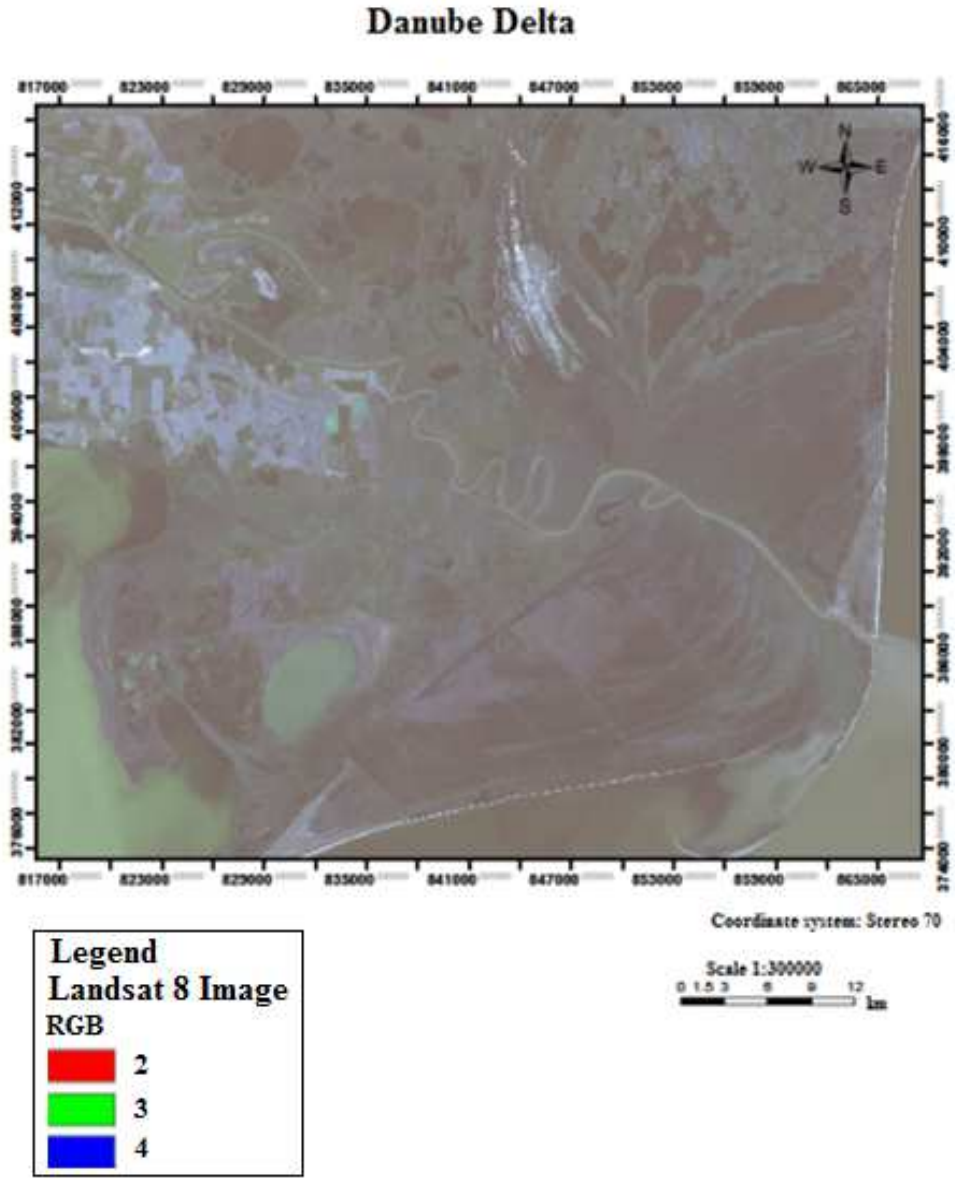

Figure 2: Landsat 8- Bands 234

3. Bands 247 (band 2 in blue, band 4 in red and band 7 SWIR). Band 7 provides information about the amount of water in the substrate and in the plant tissues. By analyzing this image, it can be seen the alluvial cone formed at the mouth of the Danube to the Black Sea (Figure 3). Furthermore, it can be noticed in the upper left side of the image the area in which cities are developed.

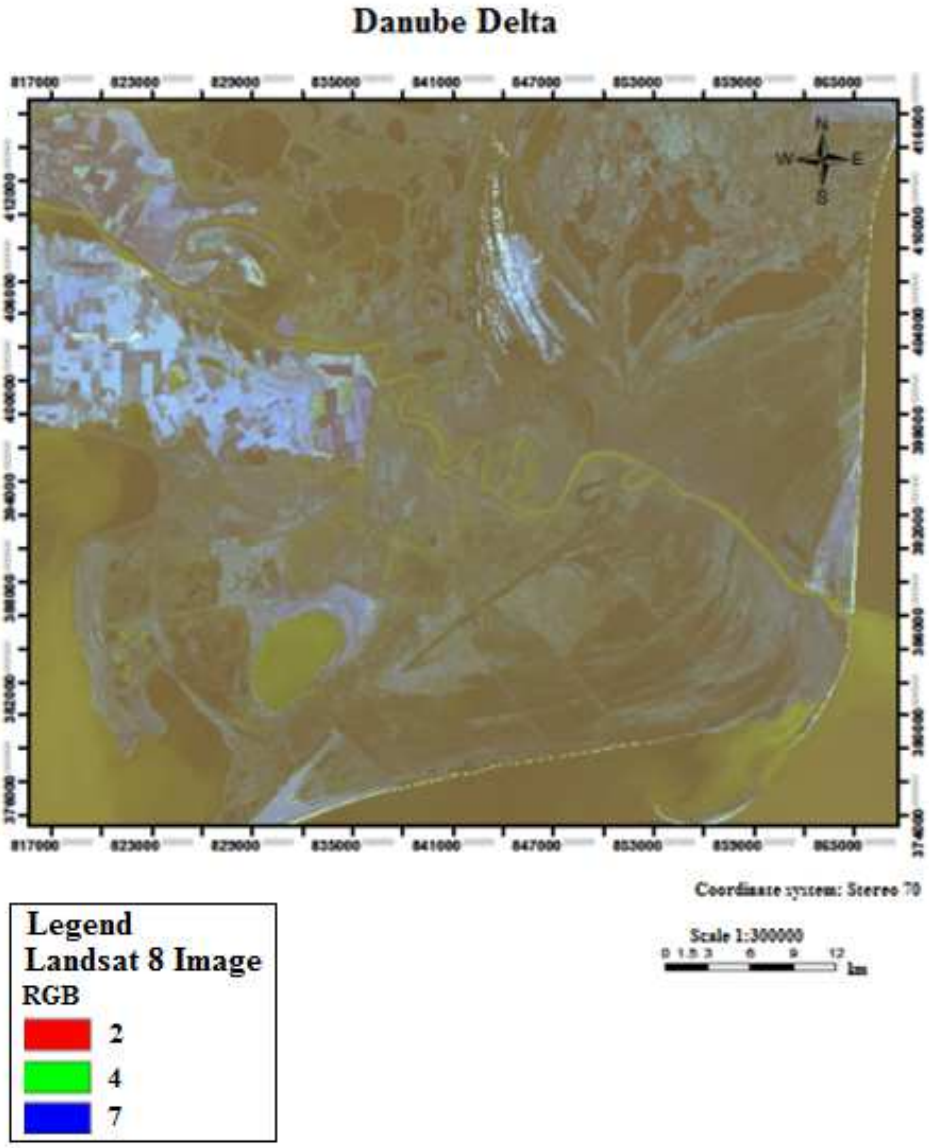

Figure 3: Landsat 8 – Bands 247

4. Bands 735 bands (Band 7 SWIR, band 3 in green and band 5 NIR). In this combination of bands, band 7 provides information about the content of water in the area. It can be observed the precise delineation of areas with farmland and areas without crops. The flooded areas of the Danube Delta are shown in green shades, and it can be observed that the alluvial cone in this image is well-defined (Figure 4).

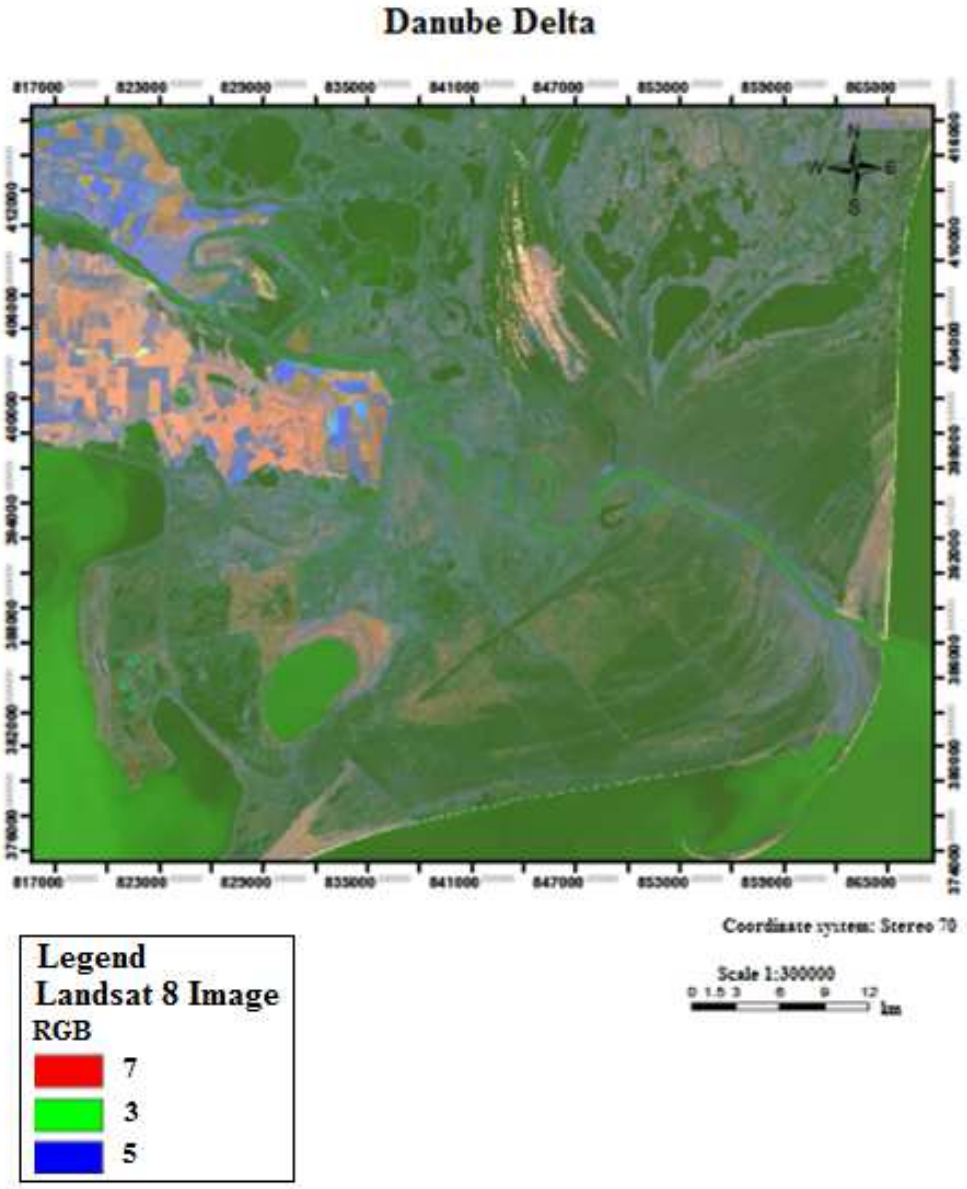

Figure 4: Landsat 8 – bands 735

5. Bands 742 lane (band 7 SWIR, band 4 in red, band 2 lane in blue). By analyzing this image, it can be observed a major difference in the combination shown above (bands 735). Through this combination, the flooded areas and the evident agricultural land area in the north- western of the satellite scene are delimitated. The Danube has a green tint which is different from the inundated zone. Also, it can be observed in a yellow color the dunes that border the Danube Delta (Figure 5).

This combination of bands has similar properties to the properties resulted from the combination of bands 453, the only difference between them being the green color of vegetation. It is worth mentioning that the Landsat 7 combination of bands 742 was selected for the global mosaic created for NASA.

The combination was used to outline the lithological units, and the structural and morphological features as well. The Bands 742 distinguish clearly between the basement rocks whereas the

difference between the bands 4 and 2 highlights the differences in lithology between pure limestone and more sand cover (Mwaniki M.W, 2015).

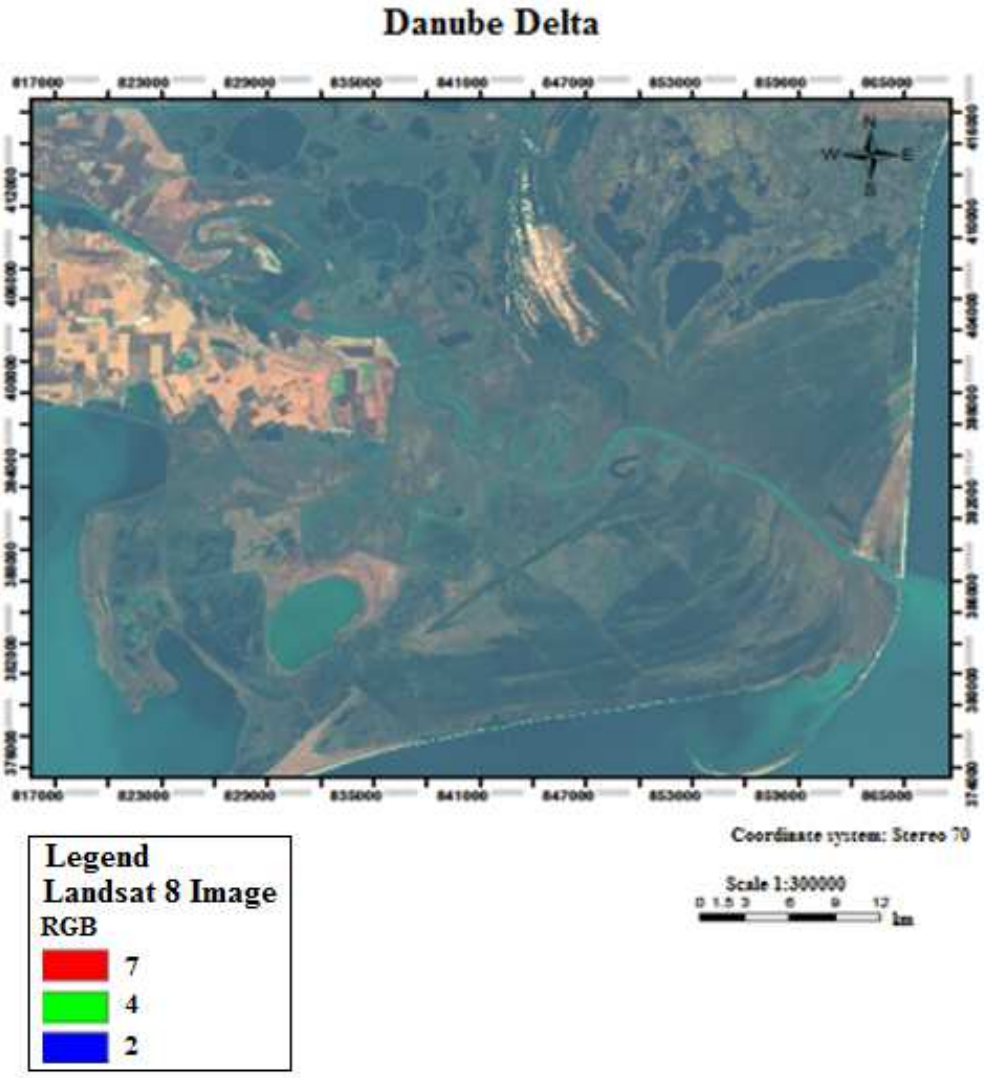

Figure 5: Landsat 8 – bands 742

Conclusion

The aim of this study was to present the possibility of using remote sensing in land changes. We would like to emphasize that the study area is one of the most important in Europe, because these lands offer the possibility to develop a sustainable agriculture.

The satellite images can help monitor the land located in Delta. In the near future, our aim is to establish a temporal evolution of land in this geographical area. For this purpose, images for a period of 10 years will be downloaded in order to identify the changes that occurred in that period of time.

Last but not least, the combination between GIS and remote sensing provided us a lot of information about the land cover of this study area and the spatial distribution of different land cover changes.

In conclusion, the satellite imagery, including Landsat 8, plays an important role in developing crop production estimates (i.e. particularly the Danube Delta area has a lot of land which is cultivated with different types of grain).

Abstract

Concerning the maritime transportation industry, according to the International Maritime Organization (the United Nations' regulatory body to ensure that the shipping industry contribution in emissions' reductions is managed effectively) CO_2 emissions have increased by almost 70 per cent in the last 25 years. As a result of the imminent threat, the European Commission together with the organizations concerned with the decrease of the pollution level and the control of the greenhouse gas emissions decided to regulate the system through the introduction of new threshold via legislative measures. The paper highlights the results of a doctoral research concerning ship owners attitudes towards sustainable strategies designed to meet the requirements of the new regulations imposed by the International Maritime Organization. The first objective is to reveal the relevant measures undertaken by shipowners to support the decrease in greenhouse gas and non- greenhouse gas emissions. The second objective concerns to what extent these measures might economically influence the organizations performance and which are the benefits of implementing the policy mechanisms within the current economic environment.

Keywords: energy efficiency, greenhouse gas, sustainability, new-buildings

Introduction

It has been established that the transportation industry comprising all its modes has to meet many requirements and fulfill the challenge of economy, society and environment (Abdallah, Belloumi and Wolf, 2013).

Nowadays, more concern within the shipping industry is given to the environmentally sustainable strategies that might decrease the impact of air pollution from ships and to reduce, even to extinguish where possible, any risk related to the sewage and harmful substances from ships. As Comtois and Rodrigue (2013) suggested, the environmental impacts of the transport modes are in a direct link with their supply energy systems, their emissions and the infrastructure over which they operate, so the efficient management of the operations, trained crews effectively guided and a deep understanding of the regulations in force are the key tools to reduce greenhouse gas.

The paper will assess shipowners approaches in their attempt to comply with international regulations and how this approach might economically influence the maritime industry. According to Endresen et al. (2008) the shipping industry represents an important contributor to the global greenhouse gas emissions as a result of the use of fossil fuel in their operations. Joumard and Gudmundsson (2010) reinforced this statement adding that transportation is a field of activity with a prominent role in the society, but raising great concerns as regards to the impact and consequences on the environment. Figure 1 highlights the rapid growth in CO_2 emissions from international shipping, as presented within the International Maritime Organization (IMO) in 2009.

Furthermore, statistics according to the International Maritime Organization suggest that under the current policy, shipping emissions are expected to rise significantly, by 50 to 250 per cent (IMO GHG Study, 2014). As a result, reducing emissions resulting from anthropogenic greenhouse gas is imperative and shipping companies are facing economic challenges as most of their fleet is not new and most of the vessels are not in compliance with the current requirements thus are in need of

conversion and technological improvements. The decision –making concerning investing in new vessels is a complex process as ship-owners face fluctuant prices of fossil fuels.

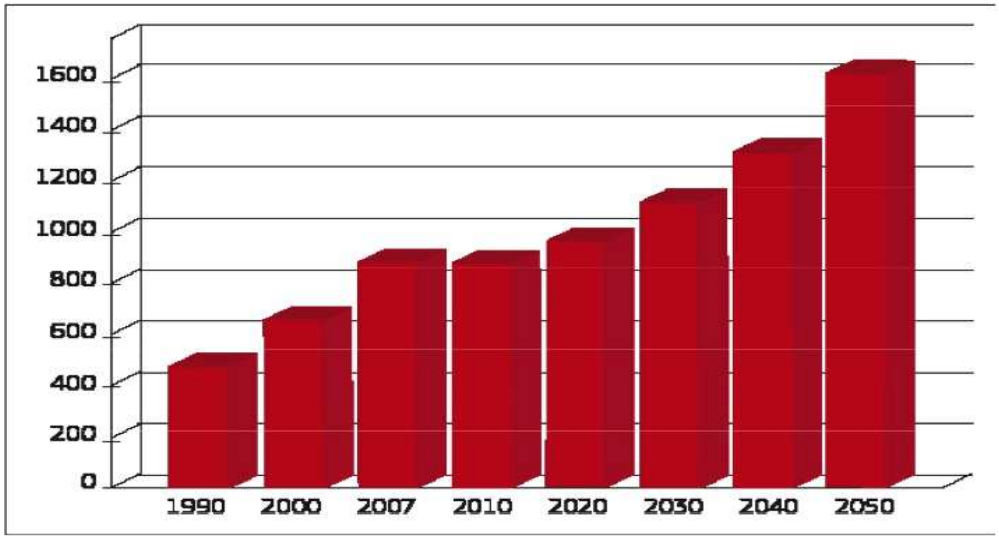

Figure 1: Estimated CO_2 emissions in million tonnes per year (Sources: 2nd IMO GHG study 2009 for emissions until 2007; MEPC 63/INF 2 for average scenario projections 2010-2050)

1. Literature Review

Climate protection, shifting to a renewable power base, reducing the energy consumption and increasing energy efficiency are the key approaches to stop global warming (Hennicke and Welfens, 2012), (Pollak et al., 2010). As a consequence, the energy economics being limited by ecological constraints (Barbian, 2001) are worldwide facing ongoing system changes. In this respect, according to Helfre and Boot (2013) the shipping industry has been given various opportunities to switch to a more sustainable behaviour.

Under the Greenhouse Gas (GHG) Protocol, six gases are categorized as greenhouse gas, CO_2 being the most relevant to the shipping industry. In addition, globally, 1,050 million tonnes of CO_2 were emitted by shipping in 2007, doubling 1990 levels (Helfre and Boot, 2013), CO_2 emissions representing approximately 3% of the world's total CO_2 emissions (Buhaug et al, 2009).

On the other hand, shipping produces other air emissions, most notably sulphur oxides (SOx), nitrogen oxides (NOx) and particulate matter (PM). It is important to establish the fact that the shipping industry is among the top emitters of SOx.

A total of 2.3 million tonnes of SO2 (the most common sulphur oxide) was emitted by ships in the seas surrounding Europe in the year 2000. Globally, 15 million tonnes of SOx were emitted by shipping in 2007, representing a 50% increase from 1997 levels. Moreover, SOx emissions from shipping represent between 5% and 8% of the world's total SOx emissions (Helfre and Boot, 2015).

IMO has defined the Emission Control Area, where more stringent rules and regulations are applicable for type of fuels and emission from ships. MARPOL Annex VI defines two sets of emission and fuel requirements: (1) global requirements, and (2) more stringent requirements applicable to ships in Emission Control Areas (ECA). An Emission Control Area can be designated for SOx and PM, or NOx, or all three types of emissions from ships, subject to a proposal from a Party to Annex VI Marpol (Hasan, 2011). There are currently various active Emissions Control Areas (ECAs) in Europe, such as the Baltic Sea area and the North Sea area (only for SOx).

In addition, IMO regulated North American area for SOx, NOx and PM; the United States Caribbean

Sea area for SOx, NOx and PM (came into force in January 2013 and are in effect from January 2014). Currently, China has published new regulations designating three areas as sulphur control areas effective January 1st 2019 (DNV GL, 2015).

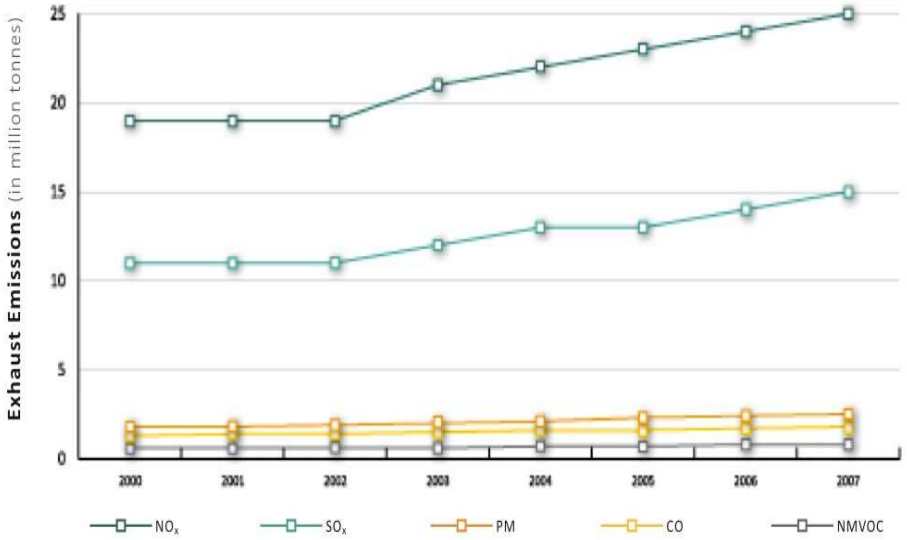

Figure 3: Global Non-Greenhouse Gas Emissions from Shipping (Source: International Maritime Organization, "Second IMO GHG Study 2009.")

2. Research Methodology

Desk research has been undertaken by the author in order to attain the objectives stated. The first objective targeted is to reveal the relevant measures undertaken by shipping companies to decrease the level of greenhouse gas and non- greenhouse gas emissions within the vessels' operations. There were analyzed theoretical considerations regarding the new regulations imposed by the International Maritime concerning the decrease in CO_2 emitted by worldwide vessels.

To achieve the second objective – namely to present to what extent these environmentally - friendly measures mighteconomically influence the shipping companies' performance, the author, based on the statistics gathered from the international organizations that monitor greenhouse gas emission, identified the costs shipping companies must support in order to meet the imposed regulations.

3. Research results concerning ship owners approaches in ensuring compliance with the European Emission Control Areas (ECA's) and the International Maritime Organization Regulations

Desk research targeted various technological measures to be the main tools in adopting more sustainable operations in the near future, based on eco- efficiency analysis. Although there is already a range of available measures in use, the most productive ones are thought to be the increase in propulsive efficiency and the increase in power production efficiency. Moreover, measures such as reduction in ship resistance and the reduction in auxiliary consumption are expected to highly increase as part of more sustainable operations.

It has been illustrated that lately, the International Maritime Organization encouraged a regime based on analysis and cost effectiveness assessments, the main tool within this process being the Formal Safety Assessment (Eide et al., 2009). Although highly technical and complex, recommendations as the result of the FSA might be a powerful tool in decision-making to prevent economic difficulties for the maritime companies in situations that their operational activities might cause negative

impacts on the environment.

However, as Eide et al. (2009) highlighted, there is number of measures, which have already been applied to reduce greenhouse gas emissions, such as emission taxes and hybrid schemes that established targets and standards within the industry. As a result of the mandatory requirements imposed by IMO, shipping companies' attempt to become green and improve reputation among stakeholders in order to reduce consumption and ultimately to gain profits has reified in a range of measures, such as technological measures that include energy- saving engines, more efficient ship hulls and designs, cleaner fuels (natural gas, alternative fuels); operational measures which include speed optimization, optimal fleet management and deployment, efficient, supply chain management, and others that impact the logistical operation. Other approach includes the market-based measures, which include the Emissions Trading Schemes (ETS), an International Fund based on a contribution imposed on fuel (Psaraftis, 2012).

Except for the care of their regulation compliance and ultimately their reputation, shipowners must protect their capital and find viable, cost- effective solutions to ensure compliance with the ECA regulations and IMO legislation. Although such procedures require substantial investments within the current technical situation of the fleet and the lack in mature technology, most of the shipping companies adopted early strategies to meet the forcoming legislation.

The Monitoring Plan of CO_2 emissions (MP)

According to the European Commission (2015) the Monitoring Reporting and Verification Regulation (MRV) system is estimated to cut CO_2 emissions by up to 2% compared with a 'business as usual' situation. Furthermore, as the International Institute of Sustainable Development (2014) stated, establishing an MRV regime will need to involve designating responsibility to regulatory entities to oversee, approve and coordinate MRV at the local, subnational, national and international levels. Roles and responsibilities have to be defined and existing capacities assessed in order to determine where capacity or policy gaps exist.

Desk research suggested that the MRV system would reduce net costs to owners by up to €1.2 billion per year by 2030.In addition, it might bring useful insights into the performance of individual ships, their associated operational costs and potential resale value (DNV GL, 2015).

As a result of all the regulations in force concerning vessels' emissions caused by their daily operations, companies with responsibility on the ships' operations have to report the results of previous year's annual monitoring of aggregated CO_2 emissions emitted. The IMO regulations lay down rules for the accurate monitoring, reporting and verification of CO_2 emissions and other relevant information from vessels above 5000 gross tonnage (GT) calling at European ports.

International Maritime Organization Energy Efficiency Design Index (EEDI)

IMO defined energy efficiency as grams of CO_2 per tonne nautical mile and IMO formulated the EEDI as a measure of a ship's CO_2 emissions. EEDI is calculated using characteristics of the ship at build, incorporating parameters that include ship capacity, engine power and fuel consumption (Rightship, 2013).

The new ships contracted as of 1 January 2013 and with delivery not later than 30 June 2015 must have an attained index at or below the EEDI reference baseline. For vessels with a building contract from 1 January 2015, the baseline is reduced by ten per cent. The baseline is further reducing for contracts placed as 1 January 2020 (ABS, 2013). As a result, this would have a bias on the implementation of energy efficiency measures for newbuildings over existing vessels (Rehmatulla, 2015) Furthermore, desk research undertaken by Faber et al (2015) has shown that the EEDI advantages for shipowners depend on the contracts, such as a vessel owner with a more energy efficient vessel can reduce their bunkers and will represent a first option vessel for ship-owners in a collapsed or through economic environment. Furthermore, while retrofits and upgrades can be costly,

the payback period can be relatively short (depending on the type and cost of the energy efficient measure chosen by the respective ship-owner). Other benefits to vessel owners might include port or terminal discounts; lower insurance premiums, avoidance to pay non-compliance surcharges and an enhanced reputation (preferred position by stakeholders and business partners).

According to the desk research undertaken, the assumption from Figure 4 is supported by information gathered from an international certification body and classification society (DNV GL, 2013), highlighting that following realistic statistics environmentally efficient designs will gradually improve throughout this decade and a new-building contracted in 2020 will, depending on type, emit 10-35% less CO_2 than a current ship with an EEDI equal to the IMO reference line. The largest reduction will be experienced with tank, bulk and container vessels.

	Size	Phase 0 1 Jan 2013– 31 Dec 2014	Phase 1 1 Jan 2015– 31 Dec 2019	Phase 2 1 Jan 2020– 31 Dec 2024	Phase 3 1 Jan 2025 onwards
Bulk carriers	>20,000 Dwt 10–20,000 Dwt	0% n/a	10% 0–10%*	20% 0–20%*	30% 0–30%*
Gas tankers	>10,000 Dwt 2–10,000 Dwt	0% n/a	10% 0–10%*	20% 0–20%*	30% 0–30%*
Tanker and combination carriers	>20,000 Dwt 4–20,000 Dwt	0% n/a	10% 0–10%*	20% 0–20%*	30% 0–30%*
Container ships	>15,000 Dwt 10–15,000 Dwt	0% n/a	10% 0–10%*	20% 0–20%*	30% 0–30%*
General cargo ships	>15,000 Dwt 3–15,000 Dwt	0% n/a	10% 0–10%*	15% 0–15%*	30% 0–30%*
Refrigerated cargo ships	>5,000 Dwt 3–5,000 Dwt	0% n/a	10% 0–10%*	15% 0–15%*	30% 0–30%*

Figure 4: Reduction factors (in percentage) for the Energy Efficiency Design Index relative to the reference line for each ship (Source: IMO, Marpol Annex Vi)

As Hasan (2011) highlighted, the EEDI can be treated as an index measure of transport efficiency, such that, the maximum amount of cargo that can be carried with minimum fuel consumption. Adopting the EEDI means that the ultimately target is to reduce the CO_2 emission from the operating vessels. As a result, by forcing the shipping industry to have more and more energy efficient ships, CO_2 emission is almost proportional to fuel consumption, and fuel consumption is the proportional reflection of total hull resistance.

On the other hand, it was found that there are other various ways of calculating energy efficiency and efficiency design, in more simple steps. As a result, the Estimated Index Values (EIV) might be used to measure design efficiency, an index in conformity with MEPC.215 (63) (MEPC, 2012).

Important to note is that EIVs should not be mistaken for EEDI scores. The EIV is more a measure of the design efficiency than of fuel efficiency of ships as there are a number of simplifying assumptions used in the calculation. Within the study Faber et al (2015) conducted, it was highlighted the relationship between EEDI and EIV by linking the ships in Clarksons' Register to the IMO database. Results described a clear linear trend is shown with a coefficient of determination (R2) of 0.92. On average, the EEDI value is smaller than the EIV or, in other word the EIV is an overestimation of the EEDI. Furthermore, by using the EIV to calculate design efficiency, according to the study undertaken by Faber et al. (2015) regarding 9000 vessels that have entered the fleet between January 2009 and July 2014, it was highlighted that container- ships have improved their design efficiency since 2009 (approximately 90% of new container ships had estimated index values below the reference line) and bulkers have improved their design efficiency since 2013.

Taking into account that the EIV is an overestimation of the EEDI, this result suggests many ships already exceed the EEDI required from 2015, concluding that EEDI is a strong driver for attaining fewer emissions.

3.1 Research results concerning the economic impact of the International Maritime Organization's requirements concerning CO_2 emissions on the shipping companies

In order to comply with regulations, companies have to invest in data analysis systems and in procedures that monitor the impact of the operations. According to Nelissen and Faber (2014) several shipping companies have, on a voluntary basis, started programmes to improve the efficiency of their fleet over the past years. These companies have not only invested in systems that monitor the fuel consumption, but also taken various other technical measures to improve fuel efficiency. Table 1 highlights the cost of implementing strategies that support sustainable operations in the shipping sector associated with the stakeholder that bear the cost.

Table 1: Overview on cost items associated with Monitoring, Reporting and Verification Regulation concerns emission of CO_2 from the shipping sector

Cost item	Stakeholder to bear costs
Familiarization with obligation	National authorities, EU authority, Ship owner/operator
Designing information material	National authorities, EU authority
Informing subjected entities	National authorities, EU authority
Developing reporting tool	EU authority
Registry costs	Ship owner
Purchase of additional monitoring and reporting equipment	Ship owner
Additional maintenance of monitoring and reporting equipment	Ship owner
Setting up monitoring plan	Ship owner
Additional monitoring	Ship owner/operator
Reporting (setting up emissions report)	Ship owner/operator
Verification of information submitted	National authorities, EU authority
Processing of verified reports	EU authority
Enforcement National authorities (if ship is inspected compliance has to be checked (by ensuring that document is on board), application of penalties, execution of expulsion order)	National authorities
Fulfilling possible recommendations from National Authorities (inspection application of penalties, execution of expulsion order, etc.)	Ship owner/operator

Source: European Union (EU) regulation 2015/757 on the monitoring, reporting and verification (MRV) of carbon dioxide (CO2) emissions from maritime transport

According to ESN (2013) report, the main barriers to making environmental investments in the shipping industry are complex and they relate to the high cost of the operations involved and also to the human approach such as the training of crews and the professional teams that manage the complexity of the installations and integration. Except for technical issues that cover the safety of the vessels and the crews, shipping companies face lack of competitive incentives

On the other hand, financial issues that affect the shipping industry arise from the current economic environment, such as the fluctuant price of the oil. Oil is the major source of energy powering the global economy, supplying approximately 95 per cent of the total energy fuelling world transport (Aleklett, 2007). Like other modes, the maritime transport relies heavily on oil for propulsion and, in view of limitations imposed by existing technology and costs, the maritime industry is highly

influenced by the price of oil (Backus, 2000).

Oil price have fallen since 2014 with consequential effects on the shipping sector with regard to price of the fuels and valuation of the companies. The vessels ordered during the market boom or shortly thereafter and now being delivered, are facing difficulties in matching today's less favorable economic situation concerning the decrease in oil price. The companies that have invested considerably in alternative means of improving consumption and exhaust gases emissions might think that their investment on such technologies is futile on the short terms, as the fuel price nowadays does not necessarily represent the main concern in vessel's operation expenses.

Nevertheless, they will have benefits on the medium and long-term, as the eventually expected recovery of the oil, products an fuel markets will reignite the focus on development of more energy-efficient systems for ships. Still on the short term, the cost of ships' fuel is expected to keep the market participants attention, as a result of the increased demand and use of (low sulphur) distillate fuel that will follow the implementation of the new IMO rules (MARPOL Annex VI) that will apply in Emission Control Areas in 2015 and globally from 2020 (DNV, 2015).

Furthermore, the vessel prototype that was developed alternative fuels like liquefied natural gas or methanol, are still non-affected by the price of fuel, but they see put on hold plans for access to a distribution network and infrastructure of such stations, storage and distribution of these fuels.

3.2 The environmental and sustainable perspective in shipping: The Liquefied Natural Gas (LNG)

According to IMO's statistics, the LNG has become a popular fuel for vessels, as a result of the new regulations imposed regarding air pollution. Companies' attempt to practice more sustainable operations reified in choosing this type of fuel, as a response to the requirements regarding less GHG emissions. LNG fuelled vessels result in the elimination of essentially all SO2 emissions, and leads to reduced NOx, CO_2, and PM emissions compared to the emissions from a typical vessel powered by marine diesel.

In addition, the demand for LNG fleet has grown, this transition being on the strength of the environmental advantages of natural gas over other fossil fuels. Jensen (2004) argued that there are various factors that contributed to this particular suffrage, the main ones being related to price competitiveness and energy efficiency. Figure 6 presents the progress of the LNG fuelled fleet emphasizing a visible growth especially in the acquisition of new buildings. This implies a doubling of the fleet over the period 2013-2018.

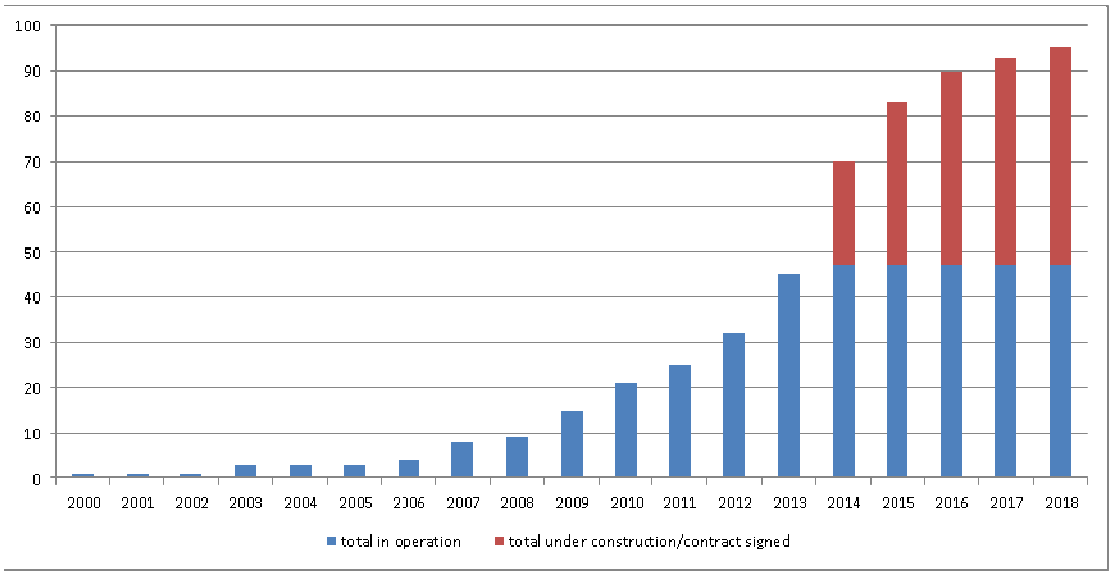

Figure 6: Development of Liquefied Natural Gas-fuelled fleet (Source: 2014, DNV, LNG for shipping - current status)

LNG's contribution to greenhouse gas emission reduction is due to its lower carbon content. As a result, as Table 2 highlights, using LNG as a ship fuel can achieve a significant reduction of pollutant emissions in the gas mode.

Table 2: Reduction potential of Liquefied Natural Gas per pollutant

Air pollutant emission (in gas mode)	Reduction potential
Nitrogen oxides	85-95 %
Sulphur oxides	-100%
Particulate Matter	-100%

Source: World Port Climate Initiative

However, as DNV (2013) stated, this approach of investing in LNG fleet might have economic advantages but also disadvantages for shipowners, as LNG has to be stored in cryogenic tanks which require much more space than traditional fuel oil tanks, fact that might reduce the cargo capacity, depending on the type of vessel and the potential to have an adequate and safe location for the LNG tanks on board.

On the other hand, although the future price level is highly uncertain due to the current unstable economic environment, the LNG is assumed to be available at a competitive cost. IGU (2015) adds uncertainty to the matter highlighting that the pricing in the world gas markets remains very fragmented, with prices influenced more by local stakeholders and regional factors than global dynamics. Summing up these findings, shipowners investing in LNG vessels might have advantages by investing in the specific field regarding the environmentally –friendly operations, but on the long-term, as demand for this type of fuel will increase as a result of the high demand in LNG vessels, will be economically affected.

4. Conclusion

Sustainable transport is acknowledged as one of the biggest challenges within the century. Regulation imposed by international organizations and environmental protection remain the key drivers of initiatives, but the economic bottom line is still dominant and it needs to be targeted in efforts by all the stakeholders within the maritime sector to deliver sustainable shipping standards (WWF, 2012).

Overall, the trend established in the new-building markets highlighted that shipping companies are investing in new vessels, like the LNG shipping market, which provide vessels recognized as being more fuel -efficient with less emissions emitted. The increasing size of many ships is also expected to improve fuel efficiency and as a result, the operational measures (e.g. better speed management throughout the course of a voyage) are also expected to reduce fuel consumption and are addressed in detail by the new Ship Energy Efficiency Management Plan that has been made mandatory by IMO. Shipping companies have a very strong incentive to reduce their fuel consumption and thus reduce their CO_2 emissions: bunker costs represent an increasingly significant proportion of ships' operational expenses, having increased by about 400% since 2000 (ICS, 2014).

Summing up the relevant information within the specialized literature, desk research has illustrated various categories of vessels that fully support the sustainable approach. The first category is represented by the ecological and economical design vessels that are built with improvements in hull form, consumption and engine power, targeted to record fuel low consumption (and thus pollutants emitted). The second category is represented by the economical and ecological retrofit vessels, which are existing vessels, equipped with facilities to reduce their consumption or are economically exploited through electronic monitoring of multiple continuous navigation and adjustment systems. The third type of vessels and the most targeted currently within the shipyards is the economical and ecological operation fuel monitoring vessels.

As the shipping industry approaches tailored strategies to become more environmentally friendly and links environmental elements with regulatory requirements, the likelihood to decrease the level of CO_2 emissions and other pollutant is higher.

Abstract

Romania is facing complaints from citizens who express their discontent with the way they are treated by public sector employees, even when they approach them in order to fulfill the obligations imposed by law, like, for example, tax payments. Currently, the computer system is not developed well enough so, citizens are forced to contact directly the public servants officials in order to satisfy their legitimate interests.The possible causes of this phenomenon in public sector are: transition from totalitarian regime to a democratic one and the low amount in wages. The present article aims to analyze to what extent should courtesy be rewarded, as a motivational method or if, on the contrary, the lack of courtesy should be penalized.

Keywords: courtesy, public servant, citizen, reward

Introduction

The situation de facto in Romania, at the present time, is a difficult one, the direct contact and generally, communication by any means of natural and legal persons with employees of local and central public institutions (civil servants) display large shortcomings concerning the manner in which the beneficiaries are treated by office holders. Direct communication between the representatives of public institutions and citizens is quite common, not only in Romania, but also in other EU countries having an information system in perfect tune. However, in the Western European countries there are very rare situations where public services' beneficiaries are not treated agreeably. One possible explanation might consist in the fact that the activity of those institutions is far better organized, the appointments with citizens being programmed individually. Thus is avoided overcrowding, standing in line for hours, circumstances in which citizens are losing their patience and time, and public servants are overpeopled and under pressure to solve the work duties in stressful conditions.

Unless it had negative consequences, the bureaucracy in Romania would be simply hilarious. This situation is further complicated by an excessive taxation imposed on individuals and legal entities. For example, for paying its property tax, a citizen needs first to queue (minimum an hour) for receiving order tickets, then queue again in order to actually pay. If additional forms need to be filled in (for example, for an office of self-employed person) one has to stand in another line so as to lodge them and then to queue again for the actual payment. If one chooses to pay online has to queue in order to receive a code based on which will make the payment.

In this context it is very easy to understand the citizens' indignant attitude and the aggressive and rude defense of public servants. It should be also mentioned that those officials at the counter are not too high in the internal hierarchy of public institutions, that they are working in a system where the principle of hierarchical subordination applies and therefore do not have too much freedom of action. But the challenging nature of the position should not be an excuse for the improper behavior that breaks the rules of professional ethics.

This paper is based on a review of the legal provisions which apply to public civil servants and of the solutions proposed for solving the problems regarding the obligation of courtesy.

I. Terminological Explanations

According to the explanatory dictionary, the short definition of courtesy (Longman Dictionary, 1998) is “polite behavior” or “things that you say or do to be polite”. In a more complex explanation, courtesy means “1. polite behavior that shows that you have respect for other people” ,”2.something you do or say in order to be polite” and courtesy by somebody or something “the permission or kindness of someone rather than by paying them” (Longman Advanced American Dictionary, 2000). On the other hand, a courteous person is someone who “has good manners and respect for other people” (Longman Advanced American Dictionary, 2000). From these explanations we can conclude that courtesy involves two components: an external one being materialized through a polite and respectful attitude and another, internal, of respect and appreciation for the interlocutor. If the external attitude can be analyzed and quantified, the internal attitude is overlooked and, we can only assume that the first is a reflection of the second. The public servants, through their work, are serving a general social interest. Their very name, “public servants”, indicates the attitude they should have during the exercise of their duties, namely to serve the citizens.

II. Legal Framework

As concerns the legislative aspect, regulation of the defining elements of the Statute of employees within the public institutions and authorities makes the object of special laws, especially regarding the public position.

Within the European Union it has been adopted Council Regulation (C.O., Euratom) No. 723/200 on 22 March 2004, this being enforced on May 1, 2004. (Spence and Edwards, 2008).

In addition to the normative act enshrining the legal status of officials and contractual employees within the EU institutions, it has also been aimed at establishing rules and principles of professional ethics, in this regard the concerns being spread due to multiple discussions resulting from the way in which European employees carried out their work, in this case, scandal that climaxed with the collective resignation of the Santer Commission on 15 March 1999 after having published the Report of Independent Experts Committee which contained allegations of fraud, poor management and nepotism in the European Commission's activity. (Spence and Edwards, 2008).

Subsequently, the Prodi Commission laid emphasis on rules of professional ethics and thus it has been adopted a Code of Conduct for Commissioners and established the Task Force for Administrative Reform which had the mission of drafting the White Paper. (Craig and De Búrca, 2009).

We mention that most European Union institutions have elaborated codes of conduct that apply to their employees, and the most important document as regards ethics and professional deontology is the European Code of Good Administrative Behaviour, document through which it is created the general framework applicable to all officials and contractual employees within the European Union institutions.

The right to a good administration, enshrined in Article 41 of the Charter of Fundamental Rights of the European Union and recognized for the EU citizens implies the existence of a body of professionals whose mission is to ensure the achievement of European interest. In this regard, The European Code of Good Administrative Behaviour has been adopted by the European Parliament in 2001 and includes deontological principles and ethical duties incumbent on the employees within the European Union structures. This document pays particular attention to courtesy (Article 12), as an obligation incumbent on the staff from the Union’s institutions.

According to Article 12, the courtesy of the public servant involves several aspects: “1. The official shall be service-minded, correct, courteous, and accesible in relations with the public. When answering correspondence, telephone calls, and e-mails, the official shall try to be as helpful as possible and shall reply as completely and accuratly to questions which are asked. 2. If the official is

not responsible for the matter concerned, he or she shall direct the citizen to the appropiate official. 3. If an error occurs which negatively affects the rights or the interests of a member of the public, the official shall apologise for it and endeavour to correct the negative effects resulting from his or hers error in the most expedient way and inform the member of the public of any rights to appeal in accordence with Article 19 of the Code." (http://ec.europa.eu/transparency/code/index_en.htm).

We note that European regulation focuses on the responsibility of EU's employees to have an amiable attitude in the relations with citizens. Thus, courtesy should govern the entire activity of public servants in their relations with citizens, whether it is about a direct contact, or a contact mediated through a form of correspondence, being given as examples phone calls and e-mails. Also, through their attitude, the European institutions employees should show fairness, which means that both a possible disadvantaging of the beneficiaries and an eventual excessive favoring are forbidden. Correctness also implies the lack of any discrimination, wether positive or negative. An official must serve the legitimate interest of the European citizen, to serve him/her in the exercise of rights and satisfaction of individual's legal interest.

The accessibility condition of public servant regards all ways of communication listed in the legal text. Whatever the manner of petition, a public employee must respond promptly and in a language accessible and understandable for the applicant. A too sophisticated expressing may lead to misunderstanding. As a matter of fact, the very idea of communication implies that between the transmitter and receiver to also exist, in addition to a communication channel, a language accessible to both. Otherwise communication is only formal and will not reach its purpose, that is, to deliver accurate and useful information from one individual to another.

Official's answer to the questions of citizens should be as accurate and complete as possible so as to enable achieving the beneficiary's purpose and exercising properly its right or complying with the obligation.

Also, courtesy means not just a polite behavior towards the public, but also helping citizens in the cases when they have not addressed to the official who has the authority to respond their requests. In such circumstances, the Union's employees have an obligation to direct the citizen to the competent official. For the work duty to be considered properly fulfilled, the official has the obligation to re-direct the application or correspondence to the competent authority. It is not acceptable an answer to the applicant, whether very politely, to direct him/her elsewhere with his/her application. First of all, for many applications or documents the law provides an express time limit within which can be formulated and failure to comply with the time limit is sanctioned by incapacity. In such situation the only acceptable solution is to re-direct the request to the competent authority and to inform the citizen in relation to this matter.

Last dimension of the obligation to be courteous refers to the cases where an official or agent of the Union causes, by his/her activity, an injury to a person, thus prejudicing his/her legitimate rights and interests. Besides the fact that he/she must make all efforts to remedy the mistake made, the official has to apologise to the prejudiced person. The European rule is formulated so as to be also observed interpersonal relationships and each person's dignity. Throughout this legal text, the moral rule implying to apologize when making a mistake becomes legal rule, being assigned to it an even higher weight. If the person to whom the rule addresses fails to comply with it voluntarily, coercive force of the state might intervene in order to ensure its observance.

At the same time, officials have the obligation to inform citizens on the possibility that, pursuant to the Code, to make an appeal within legal time limits, against the decisions they deem harmful.

In the Romanian law system, deontological rules concerning public servants are regulated by Law No.7/2004. This regulation constitutes the framework law in the field and, starting from its provisions, public authorities and institutions have to adopt regulations for organization and functioning or codes of conduct whose provisions to be in accordance with those of the law (pursuant to Article 24 of Law No. 7/2004).

Analyzing the law text can be noticed that, in the *Code of Conduct for Public Servants*, courtesy does not benefit from a regulation in such detail as the one from The European Code of Good Administrative Behaviour. Otherwise, in the Romanian law, courtesy is provided as an obligation incumbent on public servants, and this must be seen not only in relations with citizens, but also in their relations with other people who work within the institution, according to Article 12 (1). Thus, courtesy is established as an obligation from two perspectives, both concerning the relations with citizens and in terms of collegiality and relations with superiors and subordinates of public servant.

Although the Romanian legislator does not expressly provide, we believe that the obligation of courtesy subsists not only in direct relations among officials and citizens, but also in relations mediated by modern ways of communication (telephone, e-mail, fax, etc.).

A particular element of the Romanian law provisions is that it is recommended, through the Code of Conduct provisions, compliance with the rules of conduct and by natural and legal persons who get in touch with the employees of public authorities and institutions with the purpose to "increase the quality of public service". Article 12 (4) of the Code has the following content: "for carrying out social and professional relations which would ensure persons' dignity, work efficiency, as well as quality increase of the public service, it is recommended to also observed the rules of conduct provided in pars.1-3 by the other subjects of these relations." This provision can be construed as establishing the obligation of courtesy also for the public service beneficiaries, individuals or legal entities. From our point of view, we do not believe that such a stipulation is necessary, especially in a code of conduct for public servants. The law regulates separately their rights, and insulting, threatening or hiting (any form of physical, mental or moral aggression) the public officials represents, as appropriate, contravention or a crime, and is sanctioned accordingly. The recommendation addressed to citizens to behave amiably with the public servants, although it is not meaningless, does not belong to this regulatory document. Romanian law contains express provisions that protect public servants against any form of abuse or injury of their dignity.

Compliance with the rules of conduct is a legal obligation provided also by Law No.188/1999 on the status of public servants. Thus, Article 43 paragraph 3 of this regulatory document stipulates that "public servants have the obligation to observe the rules of professional and civic conduct provided by law". The legal provision refers to the legal regulations in force concerning the conduct of public servants, namely the *Code of Conduct for Public Servants.*

The legal provisions adopted by other states contain references regarding the obligation of courtesy for the public servants. Acording to the research study by Palidauskaite (2006), courtesy is mentioned as a principle of behaviour for the public servants in the the Code of Ethics adopted by other countries of the European Union.

III. Courtesy, between Sanction and Reward

Proposal for financially rewarding the public servants' courtesy appeared in a social context in which many citizens have expressed their discontent with the way they are treated by public servants in the exercise of rights and performance of obligations, particularly in the direct contact with them. Trying to harmonize the situation and appease spirits, the president of a union of public servants in Romania proposed giving financial rewards for the polite public servants. This proposal has been formulated taking into account the low level of officials' salaries. In such a situation any financial incentive would be welcome and would constitute an important motivation for changing attitudes**.** Their prime motivation to be courteous would be economic.

The question arises how reliable and particularly legal, might prove such a reward. In general, the reward means a reward that a person receives for a good thing that it did. It is obvious that a courteous attitude can only be a good thing.

But is it legal to reward the performance of an obligation? The legal provisions in force are

compulsory for their recipients. Courtesy has been established as an obligation for public sector employees even since 2004. However, the situation de facto proves that, in their work, public sector employees are showing too little courtesy in relations with the public. This legal rule has not found echo in social life and is not observed accordingly. Perhaps it would be the time to intervene some legislative changes so as to be ensured a respectful and effective communication among public sector employees and citizens. Lack of courtesy with which the individual is treated to almost every counter of the public institutions is notorious and must be remedied. It violates the honor, dignity and even mental integrity of the beneficiaries, the fundamental values of a democratic society.

One of the real problems encountered by someone who would like to financially reward public servants courtesy is the method of quantifying it. How courteous has to be an official for being considered courteous enough? How polite, solicitous and attentive? The first conclusion we can draw out of this proposal is that courtesy appreciation should come from the beneficiaries, the people who interact with officials. A questionnaire method might prove useful but is too laborious. Against all existing bureaucracy, another form to be filled in by the citizen does not seem such a good idea. The simplest method would be to mount at each counter, two buttons, one with a positive meaning (a smiley face) and another with a negative meaning (grim-faced) and the beneficiary, on leave, to press one of the buttons depending on how considers that has been treated. But obviously mounting such a system might prove to be expensive. Some institutions might afford funding from their own budget, others not. In such situation we would be facing discrimination, there would be courteous officials who could not be rewarded for the simple reason that there is not a system for monitoring their courtesy. What could they do in such a situation? Would they be obliged anymore to be courteous or would they not? And if not, the citizens' rights are violated.

On the other hand, if we look at this issue from a strictly legal point of view, the deontological duties are mandatory and must be observed. Thus, in the Romanian legislation is expressly provided that failure to comply with the rules of conduct constitutes disciplinary offence and entails liability of the guilty. Also, if by violating the deontological rules an injury is caused, the official is obliged to repair it pursuant to Civil Law, Article 23 of Law expressly provides No.7 / 2004.

Hence, from the juridical point of view, currently, in Romania, the lack of courtesy constitutes a disciplinary offense and may entail applying one of the penalties provided for by Article 77 (2) from Law No.188/1999 concerning the public servants status.

Furthermore, we should take into consideration that determining a disciplinary sanction is carried out following a legal procedure which requires an analysis of each case separately by a Disciplinary Commission, being absolutely necessary to bear in mind aspects such as: individual circumstances of the investigated person, weight of the offence, degree of guilt and consequences produced by the offence comitted. (Vedinaş, 2014).

For the failure to observe the courtesy obligation to be subject to the control and sanctioned, a complaint needs to be lodged by a person injured by the official with improper behavior. It is important that citizens be aware that they have this right to require the disciplinary investigation and sanctioning of public servant who is rude and lacking in solicitude. A complaint presented by a citizen aggressed in this way by a public institution employee should entail an objective investigation and, if the accusations are proven, application of a sanction proportionate to the weight of the offence. In this way such conducts are discouraged in the future. From our point of view, keeping the proportions among the offence weight and sanction imposes, for the case of breaching the obligation to have a courteous conduct, lighter sanctions, of moral nature. Nevertheless, in situations where the concerned official is persisting in the inappropriate behavior then the repetitive nature of such events can and should attract more severe penalties, including dismissal from the public position.

The relationship between the civil servants and the citizens is of major importance and in the study of Barbu and Orzan (2012) the authors mention that courtesy towards the public is an element that contribute in a positive manner to the improvement of the quality of the public services.

IV. Discussion and Conclusion

The financial reward of courtesy seems a viable solution in the context of socio-economic realities from Romania. The adequate legal rule is as a garment which dresses the social reality accordingly. It is obvious that the current legal provision establishing courtesy as an obligation of the public sector employees does not find its practical applicability, does not answer to the real need of citizens, nor as beneficiaries of public services or as state employees.

From another point of view we think it would be useful and advisable an amendment of Law No.7/2004 concerning the Code of conduct for public servants, in the sense of supplementing Article 12 with the provisions of the European Code of Good Administrative Behaviour. Clarifying and explaining the manner in which courtesy must be understood and practiced by public servants, in any way of communication with citizens will certainly lead to a proper conduct of the legal rule recipients. Such an amendment is also needed in the context in which Romania is a Member State of the European Union, and each European citizen could come to locate in Romania waiting reasonably to be treated by the representatives of local and central institutions with the appropriate respect and courtesy. Certainly, it should not be understood from the above mentioned that the Romanians would be worth less courtesy from public servants than other citizens of European countries, our intention was to emphasize the need for this legislative change taking into account the entire European context.

Further, to the extent that it will be possible, an objective quantification of courtesy or lack of courtesy for all public servants in relations with citizens, it does not seem insubstantial either the idea of financial rewarding polite and solicitous attitudes, but stick to the idea that such conduct constitutes an obligation and a state of normality, in no circumstances something exceptional that needs to be awarded. The right to dignity is a fundamental right of the human being and must prevail in social relations, both personal and institutional.

The Treatment of Budgetary Debts in the Romanian Insolvency Procedure

Abstract

Ensuring a balance, the equitable treatment of different categories of creditors in insolvency proceedings is an inevitable concern of any lawmaker who deals with this highly sensitive matter.
This paper aims at analysing the status regulation of the budgetary creditor in the insolvency procedure, as per the Romanian legislature in the new regulatory statute, Law No. 85/2014 on procedures to prevent insolvency, and insolvency.
The new regulation seems oriented towards the more flexible and faster collection of receivables, but results will only become apparent after a change of the mindset of all the parties concerned.

Keywords: insolvency, budgetary debts, Law No. 85/2014

Introduction

The procedure of insolvency is essentially a unitary, general, collective procedure oriented against the debtor in an insolvency situation, aiming at covering the debtor's liabilities, either by reorganising his/her activity, or by liquidating assets in his/her possession until the liabilities are settled, or by bankruptcy. Corporate bankruptcy laws have been an area of nearly constant changes in many countries over the past century. There are also still large differences in opinion among legal academicians, practitioners, creditor organizations, and politicians about what constitutes the best bankruptcy law. Omar (2014) charts the additions made by the French legislator to the insolvency framework, reformed relatively recently in 2005 and 2008, consisting in a fresh set of amendments in 2014 aimed at encouraging more take up of upstream rescue proceedings as well as improving the existing procedures.

Among the basic principles of insolvency, the Romanian lawmaker included: giving debtors a chance to effectively redress their business, either by the procedures of insolvency prevention, or by the judicial reorganisation procedure; granting equal treatment to all debtors of the same rank, and acknowledging the existing rights of the creditors, as well as observing the priority order of arrears, based on a set of clearly determined and universally applicable rules. As shown in the doctrine by Tandareanu (2016), „defining principles is extremely important, and their usefulness is to be proved in practice in case the regulation is missing or is unclear. It is believed that there is no order in the application of principles and they should be applied, if need be, simultaneously".

Making sure there is a balance, an "equitable" treatment of the various categories of creditors in the insolvency procedure is the main concern for any lawmaker dealing with this extremely sensitive issue. Since ordinarily the assets are insufficient to satisfy all creditors, conflicts of interests are unavoidable, and there is variously justifiable pressure in favour of a category or other. In many cases, if one examines the Romanian case law, among the creditors enlisted in the statement of affairs are budgetary creditors.

The following is an analysis of the regulation of the budgetary creditor's status in the insolvency procedure, as performed by the Romanian lawmaker in the new statute, i.e. Law 85/2014 on insolvency prevention proceedings and insolvency.

1. The Conception of the Romanian Lawmaker

As shown above, the main statute to be analysed is Law 85/2014 on insolvency prevention proceedings and insolvency (hereinafter referred to as the Insolvency Code), but, according to art. 342 para. 1, the dispositions of this law are to be completed, to the extent they are without prejudice to, the provisions of the Code of Civil Proceedings and the Civil Code. Also, the Fiscal Code and the Code of fiscal proceedings comprise regulations of the attributions pertaining to the fiscal organs with insolvency competences.

As a preliminary remark, it is to be seen that the budgetary arrears are too largely defined by the Romanian lawmaker in art. 5 point 14 in the Insolvency Code, comprising taxes, contributions, fines and other budgetary revenues, together with their accessories. The analysis of this statute leads to the conclusion that they also include, and place under the same protection, fiscal and non-fiscal arrears, such as the sums owed to the central or local budget, including the revenues derived from economic activities.
Endorsing the view expressed in the Romanian doctrine, it is our opinion that such a priority has no justification able to provide a superior position in the procedure as compared to other commercial creditors, as such a vocation belongs only to the arrears derived from the public interest function of procuring fiscal resources for the state/ local communities (Bufan, 2014).

According to the Report of uniformity of insolvency legislation on an European level, drawn up by experts from INSOL Europe, in the European Union (EU) the treatment of budgetary creditors in the insolvency procedure is differently regulated. Thus, the national statute of certain member states, such as Germany, France and Sweden does not grant the fiscal creditor a privileged order of satisfaction. There are also legislations that grant the fiscal creditor a legal preference clause, but only to a certain extent or specifically for certain types of fiscal debts (Italy, Spain, Poland, United Kingdom). In the Report on Standards and Codes (ROSC) 2014, The World Bank recommended Romania to reposition the fiscal creditor on an equal level with the unsecured creditors.

Adopting a different position in comparison with the developed states in UE and without taking into account the recommendation of the World Bank, the Romanian lawmaker granted preferential treatment to all budgetary creditors, irrespective of the fiscal or budgetary nature of the debt or the amount of the debt.

In our opinion this position may be partially accounted for by the circumstance that certain debtors, who have proper commercial relations but are bad fiscal debtors, resort to the insolvency procedure in order to be able to have operational activity under the circumstances of generalised blockage (garnishment, levy) imposed by the fiscal bodies.

2. The Test of the Private Creditor

According to ROSC, "the regulation environment, especially in regard to fiscal authorities, does not sufficiently support corporate reorganisations and other means of prevention. There are common mentions on the alleged inability of fiscal authorities to participate in operations of reorganisation and schemes (concords), by virtue of the lack of legal quality, but also because of the EU norms on state aids".

The analysis of EU legislation and case law leads to concluding that the choice of such a position by fiscal organs is not justifiable. Thus, according to article 107 para. (1) TFUE, except for the derogations provided for in the treaties, the following are considered incompatible with the internal market the state aids or aids granted through state resources, under any form, denaturing or threatening to denature competition by favouring certain enterprises or producing certain goods, to the extent in which they affect fair trade among the member states.

Nevertheless, the requirements that a measure should meet in order to qualify as ”aid” in the sense of article 107 TFUE are not met if the beneficiary enterprise could obtain the same advantage as the one put at its disposal by the state resources in circumstances corresponding to the normal market conditions (see in this respect the Decision of 5 June 2012, Commission/EDF, C-124/10 P, point 78 and the Decision of 24 January 2013, Frucona Košice/ European Commission, C-73/11 P, point 70). This assessment comes into being when a public creditor grants payment facilities for a debt s/he has towards an enterprise, by applying, in principle, the criterion of the private creditor. Thus, this criterion, when applicable, is among the elements that the Commission is bound to take into consideration in order to prove the existence of such an aid (see in this respect the Decision of 29 April 1999, Spain/Commission, C-342/96, Rec., p. I-2459, point 46, the Decision of 29 June 1999, DM Transport, C-256/97, Rec., p. I-3913, point 24, as well as the Decision of 5 June 2012, Commission/EDF, C-124/10 P, points 78 and 103, and the Decision of 24 January 2013, Frucona Košice/ European Commission, C-73/11 P, point 71).

In keeping with European regulations, the Code of Insolvency introduces a new element in Romanian legislation, i.e. the ”test of the private creditor”, whereby budgetary creditors may check if accepting a restructure plan may constitute a state aid. According to art. 5, point 71 in the Code of Insolvency, ”the test of the private creditor is the comparative analysis of the degree of settling the budgetary debt by relating to a diligent private creditor, within a procedure aimed at preventing insolvency or reorganising, as compared to a bankruptcy procedure. The analysis is based on an assessment report drawn up by an authorised evaluator, appointed by the budgetary creditor, and it is reported including to the duration of a bankruptcy procedure as compared to the payment schedule proposed. It is not state aid if the test of the private creditor certifies that the distributions that the budgetary creditor would receive in the case of insolvency prevention or reorganisation are higher than those received as a result of a bankruptcy procedure”.

An initial observation is that, taking into account the pre-eminence of the European Union law, including the case law of the Court, evinced in art. 230 Fiscal Code, this statute need not have been introduced, as the European principles being applicable de jure. However, in the circumstance that the derogations granted to this issue by the Court of Justice of the European Union are not very recent and upon their settlement the attitude of the budgetary creditors remained unchanged, we consider that the Romanian lawmaker was right to clarify this issue. Since the enactment of a statute is not enough to change mentalities, we favour the opinion expressed in the doctrine, viz. ”it is necessary to complete the insolvency law with an internal procedure at the level of ANAF; the lack of a special procedure, well designed and implemented, which would obviously presuppose a series of check-ups and hierarchical approvals would lead in the future to the inefficiency of the new statute. The reasons are varied: lack of practice with such procedures, inherent suspicions in such situations, the absence of a body of experts able to guarantee the accuracy of the necessary assessments” (Bufan, 2014).

Another important observation is that, although it was stated that the appointment of the certified evaluator is the task of the budgetary creditor, it is not clear what funds are allotted to pay for the latter’s services. As the evaluator’s activity will take place, in principle, to the benefit of the insolvency procedure, we consider that this pay should follow the principles imposed by art. 39 in the Code, i.e. to be

taken out of the debtor's assets, with the approval of the Creditors' board ad only in case the available monetary funds are insufficient (which is unlikely when a reorganisation plan is proposed) from the Liquidation fund.

It is considered that the appointment of the evaluator by the budgetary creditor is a salutary idea from more points of view. On the one hand, it is a means to clearly distinguish between the necessary report to effect the test of the private creditor and the evaluation report necessary to draw up any reorganisation plan, according to art. 133 para.4 letter d in the Code of Insolvency (the reorganisation plan should mention "what damages are to be granted to the holders of all types of arrears, as compared to the estimated value that may be received by distribution in case of bankruptcy; the estimated value is to be calculated according to an evaluation report, drawn up by an evaluator appointed according to the provisions in art. 61"). On the other hand, it cannot be stated that the report of this evaluator could be biased or influenced by the holder of the reorganisation plan, even if the latter is the debtor and the pay is granted from its available funds.

3. Including Budgetary Creditors in the Claims List

Sometimes, going through the stages imposed by the insolvency procedure as fast as possible makes the difference between a successful reorganisation and a failed one, ending in bankruptcy. Also, making crucial decisions regarding the debtor's situation is conditioned by constituting the Creditors' Assembly, and the Creditors' Committee, respectively. In this respect, it is desirable that the procedure of declaring arrears, checking these arrears by the judicial administrator , and putting together the final form of the creditors' table should take place with expediency. On the other hand, in order to observe the right to defence, it is necessary for all the creditors to have the time to acknowledge the opening of an insolvency procedure and formulate the outstanding debt statements. This is why the Code of Insolvency lays down imperative deadlines for the formulation of arrears, (according to art. 100 para.1 letter B in The Insolvency Code, this deadline is at most 45 days since starting the procedure) and the formulation of potential appeals to the preliminary table of outstanding debts (according to art. 111 para.2 in the Insolvency Code, "appeals shall be submitted to the court within 7 days since the publication of the preliminary table in the BPI, both in general procedure and in simplified procedure").

On the other hand, fiscal arrears are settled as a result of a rigorous procedure, regulated by the Fiscal and Fiscal Procedure Code, guaranteeing for the reality of the economic operations as well as the taxpayer's rights, and it requires to be observed within a suitably long time span in order for the fiscal control to be adequately implemented. In such circumstances, it is obvious the need for more time given to the fiscal creditors (Bufan, 2014). Moreover, there is also another justification of this priority: the fiscal authority can only evaluate its own situation on the basis of the taxpayer's statements or the results of the fiscal inspections, so that the "insolvency" statement of the taxpayer may constitute a presumption that the real fiscal debts– which are undeclared – are higher than the ones in the fiscal authority's registers.

By means of the new regulation, the Romanian lawmaker tried to harmonise the two contradictory tendencies in multiple ways. Thus, art. 66 para.1 in the Code states that "the debtor in an insolvency state shall submit a request to the court in order to come within this statute, within 30 days at most since the occurrence of the insolvency state. The request to the court shall enclose the proof of notification addressed to the competent fiscal organ regarding the intent to open the insolvency procedure". Art. 72. para.2 in the Code stipulates that when the request is formulated by the creditor, "within 48 hours since the creditor's request is registered, the court shall communicate it to the debtor and the competent fiscal body". Concerning the fact that the lawmaker did not state the sanction for not attaching the proof of

notification addressed to the competent fiscal body regarding the intent to open the insolvency procedure, the doctrine says that there is no sanction for not fulfilling this requirement.

The corroboration of these texts leads to the idea that the fiscal authorities shall be notified prior to other creditors about the possibility to initiate an insolvency procedure, thus having the necessary time to start the fiscal control and issue the title of outstanding debt. On the other hand, the doctrine pointed out that „within this interval, albeit short, the fiscal authority may try to consolidate its position, constituting garnishes or liens on certain goods belonging to the debtor; such a procedure seems to get in conflict with principle no. 6 on "the recognition of the existing rights of the creditors and observing the priority of arrears, based on a set of clearly stated and uniformly applicable rules". This principle may be opposed to creating preferential regimens for certain creditors in the interval immediately before initiating the procedure. Thus, the obligation to notify the fiscal authority about submitting a procedure opening request, stated in art. 66 (1) and 72(2) should be unable to lead to creating, within that interval, a mortgage or lien to the benefit of the fiscal creditor, etc. Another measure taken by the Romanian lawmaker was to grant budgetary creditors a supplementary term to finalise their arrears. According to art. 102 para. 1 in the Insolvency Code, ”budgetary creditors shall register the admission request for the arrears with the time limit stated in art. 100 para. (1) letter b), followed by, within 60 days since publication in the BPI of the notification on the procedure initiation, the registration of a supplement of the admission request of the initial arrears, if need be”.

The statute mentioned above brings another very important clarification, showing that ”there are previous arrears, and the budgetary arrears found by a fiscal inspection report drawn up after the initiation of procedure, but whose subject is the debtor’s previous activity. Within 60 days since the publication in the BPI of the notification on procedure initiation, the fiscal inspection body shall perform the fiscal inspection and draw up the fiscal inspection report, according to the Government Ordinance no. 92/2003 on the Code of fiscal procedure (…)”. In practice, attention was given to the issue of the compatibility of the dispositions referring to the request to resubmit the term, included in the Code of civil procedure with the dispositions on the obligation of fiscal authorities to observe the time limit of submitting the arrears statement and, the supplement to the admission request of the initial debt. Thus, according to art. 186 para.1 Code of civil procedure,”the party who missed a procedure deadline shall be rescheduled only if it proves that the delay was due to thoroughly justifiable reasons”. By Decision no. ……/2016 of the Appellate Court of Brașov (unpublished) it was held that granting the privileges stated in art. 72 para. 2 and art. 102 para.1 in the Insolvency Code was included by the lawmaker precisely in view of overcoming the difficulties of performing the fiscal control and obtaining the title to outstanding debts, so that these cannot be also claimed in a request to reschedule the supplement to the admission request of the initial debt.

Another issue related to including the budgetary creditors in the creditors’ table is to check the arrears. According to art. 105 para. 2 in the Insolvency Code, ”it is not allowed to perform the checking procedure (by the insolvency practitioner or the syndic judge) on the budgetary outstanding debt resulting from an executive title uncontested within the time limit stipulated in the special statute”. Also, according to art. 75 para. 3 "it is impossible to suspend (…) legal action for the determination of the existence and/or amount of the arrears of the debtor, issued after opening the procedure. For such actions it is possible to formulate, during the observation and reorganisation period, the payment request to be analysed by the judicial administrator while observing the provisions in art. 106 para (1), properly applicable, without including these debts in the outstanding debt table. The measure order by the judicial administrator may be contested by observing art. 59 para. (5), (6) and (7). "According to art. in the Code of fiscal procedure, "by waiver from the dispositions in art. 75 in Law no. 85/2014, the fiscal administrative documents issued before and after becoming insolvent are subject to the control of specialised courts of fiscal administrative

law". Art. 146 para.3 in the Code shows the fact that "all arrears targeting the debtor's possessions will be checked, including the budgetary ones, issued after the date of the procedure initiation, or, as the case may be, whose amount was altered as compared to the final outstanding debt table or the payment plan in the reorganisation plan, as a result of the payments made after opening the procedure".

The corroborated interpretation of these statutes lead to the existence of three situations. Thus, when the executive title includes liabilities prior to the moment of opening the insolvency procedure, and was not contested according to the dispositions of the special statute, it shall not be checked later. When the executive title comprises liabilities prior to the opening of the insolvency procedure and was contested, the legal action against it being ongoing, the arrears shall be provisionally included in the creditors' table (with a suspended right to vote and to participate in distributions), and the legal action shall be settled by the fiscal litigation courts. It is our opinion that the special statute in the Code of fiscal procedure should be interpreted as being within the competence of the administrative courts to deal with the fiscal administrative papers issued before and after initiating insolvency, when they refer to fiscal debts prior to the insolvency initiation, as the waiver is only in regard to the dispositions of art. 75 in the Insolvency Code, and not to art. 146. However, when the executive title includes duties subsequent to the insolvency initiation, it shall be checked by the syndic judge.

Ordinarily, there are only a few cases in practice when income tax is due after procedure initiation, but there are many cases dealing with the VAT on the transactions performed after the procedure initiation, the salary tax and the social contributions and they debts to the local budgets, derived from the mere existence of property, based on the tax due for buildings, special constructions, grounds, parking lots, etc.

It is our opinion that such a choice on the part of the lawmaker is not justified. The infringement of the specialisation principle may be admitted in case of sufficiently strong arguments. Alternatively, the issue of the rapid settlement of legal actions is not real, as administrative courts are also bound to solve cases with expediency (art. 17 in Law no. 554/2004 of administrative law). Also, there may be occurrences when the same title is aimed at determining fiscal debts covering both a period prior to, and another subsequent to opening the procedure. In such a case the same title may be attacked both in the administrative courts, and in front of the syndic judge. Finally, there may be situations when the debtor submits the statement for VAT reimbursement, and the fiscal body, assessing that the debtor has also performed transactions requiring WATT, issues a taxation decision. According to the dispositions art. 167 para.11 in Law no. 207/2015 on the Code of Fiscal Procedure, "for the debtors coming within the statute on insolvency who submit a negative-value tax discount on the VAT with the reimbursement option after the date when the insolvency procedure was initiated, the amount approved for reimbursement is compensated with the fiscal duties issued after the insolvency initiation". The complaint against it shall be settled by the syndic judge, although the competent court to reject the VAT reimbursement request pertains to the administrative court.

Concerning the issues that may occur in practice, it is our opinion that it would be best to go back to the previous regulations, when the solution to the legal actions against fiscal titles was exclusively the task of specialised courts in administrative and fiscal litigation.

4. Involving the Responsibility of Culprits for the Debtor's Insolvency State

According to art. 169 in the Insolvency Code, „the judicial administrator, the judicial liquidator, the Creditors' Assembly or the creditor owning at 50% of the debts owed may require that all or part of the liability of the debtor, physical person in an insolvency state, without exceeding the damage directly linked to the act in question, be settled by the members of the management and/or supervision boards in

the society, as well as any other individuals who have contributed to the debtor's insolvency state by means of one of the following acts:

a) used the goods or credits of the legal person in their own benefit or the benefit of another;
b) operated activities of production, trade or service in their own interest under the cover of the legal person;
c) decided, in their own interest, to continue an activity obviously leading to the insolvency of the legal person;
d) kept false accounts, obscured certain accounting documents or failed to keep books according to the law. In case the accounting documents were not remitted to the judicial administrator or liquidator, the guilt as well as the causality link between the act and the liability are presumed; presumption is relative;
e) embezzled or hid part of the legal person's assets or falsely increased the debtor's liability;
f) used ruining methods to procure funds for the legal person, to the purpose of ceasing payments;
g) in the month prior to the cessation of payments, paid or decided to pay a preferential creditor, to the detriment of other creditors;
h) any other intentional act, contributing to the debtor's insolvency, according to the provisions of the present title".

According to art. 25 para.2 in the Code of Fiscal Procedure, "the outstanding payment duties of the debtor declared able to pay in the circumstances of the present code, are to be settled in solidarity with the debtor by the following categories of individuals:

a) physical or legal persons who, prior to the date when insolvency was declared, with malice aforethought and by using any means, acquired assets from the debtors who had thus reached insolvency;
b) administrators, associates, shareholders and any other persons who caused the insolvency of the indebted legal person by ill-willingly remising or hiding the debtor's assets;
c) administrators who, during their term, with malice aforethought did not comply with their legal duty to require the competent court to open the insolvency procedure for the fiscal duties pertaining to that period and left outstanding at the date when insolvency was declared;
d) administrators or any other persons who ill-willingly determined the failure to declare and/or pay the fiscal duties when due;
e) administrators or any other persons who ill-willingly determined the reimbursement of amounts from the general consolidated budget without being duet o the debtor".

The analysis of these legal provisions leads to the fact that the special legal dispositions applicable to fiscal creditors allow the liability of persons who determined the insolvency state and thus caused them prejudice. The scope of individuals against whom these measures may be taken is roughly the same, but in addition to the dispositions in the Insolvency Code, even third person who are will-willed who acquired in any way assets from the debtors who thus provoked insolvency may also be made liable.

It is our conclusion that, however, if in order to involve the responsibility based on the Insolvency Code indirect intent is enough as form of guilt, the Code of Fiscal Procedure imposes that the act be done „with ill-will or malice aforethought", viz. direct intent. Concerning this duality of legal grounds in imposing liability on the persons affected by insolvency, in practice there may be cases when the fiscal authorities issue decisions of unitive involvement of responsibility on their behalf and, at the same time, promote actions in order to involve them in patrimonial responsibility according to the Insolvency Code. Since both the legal motivation and the finality are different, as in the former case the guilty party being executed by the fiscal creditor, to his sole benefit, and in the latter case to the benefit of all creditors, the

distribution being made according to the final arrears table, there is no ground for obtaining two executive titles.

However, it is our consideration that, in the context of simultaneous legal pursuits, the debtor shall be able to contest the executive title on the ground that the fiscal creditor in question was paid, as otherwise the latter would be getting rich without legal justification. In the particular case when the fiscal authority is the only creditor claiming outstanding debts, an action concerned with involving the patrimonial responsibility according to the Insolvency Code started after the issue of the decision of unitive involvement of responsibility according to the Code of fiscal procedure would seem devoid of interest.

5. Treatment of Fiscal Arrears as a Result of Bankruptcy

According to the dispositions of art. 140 para 1 in the Insolvency Code, after a reorganisation, ”in case of bankruptcy the situation shall revert to the initial decided in the final table of all arrears against the debtor as per art. 112 para. (1), subtracting the amounts paid during the reorganisation plan”. Consequently, the creditors shall be re-included in the table with the amount accepted originally, minus the potential amounts already recovered, so that they are entitled to recover, in bankruptcy, the VAT on the outstanding debt, and not just the debt included in the reorganisation plan. According to art. 154 para. 2 in the Insolvency Code, ”liquidation shall start immediately after the completion by the judicial liquidator of the inventory and the submission of the evaluation report. The goods may be sold as a whole or individually. Any bulk sale of the goods, as a functional sub-assembly, no matter if it is done as reorganisation or bankruptcy, may be considered as transfer of assets, if it meets the requirements in art. 128 para. (7) in Law no. 571/2003”. The provisions in the Fiscal Code referred to in the text above state that ”the transfer of all or part of the assets, occasioned by the transfer of assets or, according to the specific case, the transfer of liabilities as well, no matter if it is performed as a result of the sale or operations such as division, fusion, or nature infusion to the capital of a company, does not constitute goods delivery if the beneficiary of the assets is a taxpayer. The receiver of assets is considered as the successor of the giver in point of the adjustment of the deduction right under statute”.

Hence, the functional sub-assembly shall also be considered from a fiscal point of view as a "transfer of assets", and this bulk sale is not subjected to VAT and the beneficiary will also acquire by this transfer the bankrupt entity’s rights to VAT adjustments.

Conclusions

The analysis of legal dispositions leads to the idea that the Romanian lawmaker has strayed quite a lot from the international recommendations to place fiscal creditors on the same legal position as the other creditors in the insolvency procedure, both by the dispositions of the Insolvency Code, and the special dispositions in the Fiscal Code and the Code of Fiscal Procedure. On the other hand, by taking over European case law on the analysis of the reorganisation admitted by the fiscal creditor versus state aid, the Romanian lawmaker followed the international recommendations in granting a second chance to honest debtors.

The new regulation seems more flexible and oriented towards the more rapid collection of budgetary/ fiscal arrears, but the results will be apparent only as the aftermath of a change in mentality of all those vested in the procedure.

Abstract

One of the most important issues that occur in the process of traceability systems for fishery development is to take in consideration all the aspects connected with the fishery supply chain. This involves balancing the point of view of all the stakeholders from the fishery supply chain. This paper aims to provide information on consumers' perception and their attitude regarding quality and safety of fish products, purchasing behavior, and willingness to buy safe fish products in Romania, based on a survey of fish products consumers. The results show that the price, the knowledge concerning processing, storage, and the traceability system of the fish products, are the main determinants of Romanian consumers for the traceable products.

Keywords: traceability systems, fishery supply chain, consumers, quality, safety

Introduction

Until the late 80s, Romania had an important fish processing industry, that, ten years later, to fall into a steep decline. The situation was caused, on the one hand, by a drastic decrease in production due to the closure of fleet for ocean fishing, and on the other hand, by the consumer preferences for new imported products that the Romanian companies could not offer on the market. At present, the yearly consumption of fish in Romania is 5.5 kg / capita, while in the EU countries fish consumption is on average 20 kilograms per person per year, the largest consumers being Portugal and Spain with 48 and 45 kg per capita/year (Aquaculture, Fishery Businesses in Romania, 2016). The fish consumed in Romania comes either from domestic production or from imports. The internal production is represented by the catch from commercial fishing, both in the inland waters, and in the Black Sea, aquaculture, raising fish in guided system, in pools, ponds and basins. The fish is delivered fresh or processed in different stages, and then traded. Fish farming in Romania includes aquaculture, marine fishing and inland water fishing, as well as processing activities. The most important activity is aquaculture in freshwater, being followed by fishing in inland waters. In Romania there are fish production facilities in 38 counties. There are over 84,500 ha of fish breeders, 15,500 ha fish nurseries, 300 fish farms and 60 trout farms with an area of 44 ha (Raising fish in Romania, 2016).

In the last years, some Romanian companies have begun to offer modern products and the domestic production, especially semi-prepared products, started to go up again. In order to have a market of functional fish products, at the national level, it is intended to adjust production at the demand level, for the benefit of both producers and consumers. Fish market organization is based on the adoption of commercial standards for quality, size, packaging and labelling of fresh fish. Stakeholders have different traceability requirements, distinct ways of approaching, given by the different parts they have in the distribution chain of fishery products. The implementation and use of traceability system depends on the close cooperation among the parties involved in the distribution chain. If the traceability system meets the requirements of all participants - consumers and producers, then the benefits anticipated will be achieved. In this respect, information gathering has been carried out by

taking into account the main stakeholders from the sale chain of fishery products, that is, consumers and producers, who include: farms specializing in the production of young, breeders, companies producing and companies dealing with the sale. The factors driven by the market influence the sustainability of the fish and seafood supply chain (Peterson and Fronc, 2007).

The research undertaken at this stage determines consumers' perception and their attitude regarding quality and safety of fish products, purchasing behavior, and willingness to buy safe fish products in Romania.

1. Methodology

The method used for collecting information is questionnaire. Questionnaires designed for consumers aimed at determining the factors that influence the decision to buy fishery products. The questionnaire intended for determining the key factors in implementing information systems for quality traceability in companies from the agricultural sector consists of three sections, as follows: demographic details (the environment in which it lives – urban/rural, gender, job category, level of education) and respondent preferences (consumption preferences, purchasing behavior and criteria taken into consideration on the purchase of fish and pisciculture products), factors influencing the decision to buy fish /fishery products (product price, apparent freshness, term of validity, fish origin, conditions in which the fish was raised (water, soil), conditions in which the fish was fed, conditions in which the fish was transported, conditions in which the fish was stored, conditions in which the fish was processed) and traceability-related factors that influence intention to buy fish / fishery products in the future (availability of information as regards the quality of fishery products, the availability of suitable labeling, accessing information related to the quality of fishery products).

The respondents were asked to evaluate their responses on a Likert scale of five points (from 0 to 5), ranging from totally agree to totally disagree. 800 questionnaires were distributed and returned. After eliminating those questionnaires with incomplete responses and those otherwise unusable, 743 usable questionnaires were obtained. The statistical analyses were conducted using SPSS software. Mean responses with standard deviation, frequencies and percentages of responses in each category were calculated and presented in tabular form.

2. Results and Discussions

Consumer preferences and purchasing behavior when purchasing fish and fishery products

Freshness is an important factor that affects the fish consumption in Turkey. The research conducted by Can, Günlü and Can (2015) shows that most of the questioned consumers (98%) preferred fresh fish to processed fish. Table 1 shows the purchasing behavior of Romanian consumers surveyed. Most consumers preferred to purchase refrigerated fish (24.60%) and live fish (20.16%), rather than frozen or processed. The primary processed products, such as whole frozen, were more popular than deep processed products, such as fillets or fish balls or sea fruits.

Table 1: Respondent's preferences

Which of the following products from fish and fishery products are preferred by you?	**Percent**
Live fish	20.16
Refrigerated fish	24.60
Frozen fish	13.10
Semi-canned fish	13.36
Canned fish	16.94
Seafood	11.84

A survey conducted in the United States showed that seafood is purchased most from supermarkets, street sellers, and restaurants (Sechena et al, 2003). In Turkey, it was found that fish is most frequently purchased from fish markets (80%) and supermarkets (Can, Günlü**,** and Can**,** 2015). The majority of the Romanian consumers (34.35%) preferred to buy fish products from fisheries. Approximately 33.87% of consumers buy fishery products from supermarkets and hypermarkets. At the opposite pole of preferences regarding the place from where consumers choose to purchase fish and fish products, are the producers and proximity stores, as shown in Table 2.

Table 2: Purchase behavior and criteria taken into account when purchasing fish and pisciculture products

From where are you buying fishery products for own consumption?	Percent
Supermarket/hypermarket	33.87
Fishery	34.35
Food market	12.07
Food store/ proximity store	7.91
Directly from the producer	11.80

Factors that influence the decision to buy fish and fishery products

Several factors are affecting on the demand of fish and fishery products. De Silva (2011) identified the price, the income, the income distribution, the substitutes, the tastes, the fashion, and advertising and expectations of the consumers as the main factors. Also, he stipulated that ethnicity is other important determinant of the demand. Countries in the East place have a high demand on wide variety of fish and fishery products in comparison with the other parts of the world. Moreover, countries with larger Muslim population place high demand on meat products than fish. A study focused on the exploration of the cross-cultural differences in the frequency of fish intake and motivation for fish consumption among people was conducted in five European countries (Pieniak et al, 2008).

The results of the survey conducted in Romania, presented in Table 3, show that the consumers' behavior have some particularities, in comparison with the results of the other surveys operated in other areas of the world. The most important incentive factors that affect the purchasing decision for fish and fishery products are the product price and the conditions in which fish was stored, followed by the conditions in which the fish was fed, and the conditions in which the fish was transported. Except the price, all factors highlight the relation to the quality and safety knowledge and risk perception, which contrasts with the results of a similar study /survey carried out in PR China, which shows that the consumers reveal an obvious lack of quality and safety knowledge and risk perception associated with fish products (Wang et al., 2009). Maintaining the cool chain is essential to minimize product deterioration and to maximize the shelf life of the product. Many potential problems in the supply chain can be avoided by understanding the critical handling issues and carefully planning each load.

Table 3: Factors that influence the decision to buy fish/fishery products

Influence Factor	Composite Priority	Rank
Price of the product	12.325	1
Apparent freshness	10.979	4
Term of validity	10.612	6
Fish origin	10.317	7
Conditions in which the fish was raised (water parameters)	10.837	5
Conditions in which the fish was fed	11.635	2

Conditions in which the fish was transported	11.500	3
Conditions in which the fish was stored	12.325	1
Conditions in which the fish was processed	10.979	4

Quality and safety awareness and intention to buy fish and fish products

The consumers become more concerned about food safety than ever before and markets such as European Union (EU), Japan and the United States (US) have strict regulations to ensure quality and safety of fish and fishery products. Food labelling has to provide information about the product composition, safety information and origin. This means that all fish and fishery products have to have labels, which provide information about the origin and the means of production (farmed or wild). Quality standards add extra cost to the production process and quality requirements differ from market to market. Thus, EU market is based on as EU directives food safety and sanitation, and US market is based on US Food and Drug Administration (USFDA) requirements, whereas Japanese market is based on Food and Sanitation Law (Lupin, 1999).

Many respondents indicated in the survey they are aware by the certification strategies (traceability and quality labels) developed to improve consumers perception of food safety where food safety. This shows that the Romanian consumers are informed about the importance of quality and safety of fish products. The Chinese consumers place low value on the indication of quality control. As a whole, respondents indicate they are willing to pay a 6% premium over the price for traceable fishery products (Wang et al, 2009). Concerning the access to information in relation to the quality of fisheries products (traceability), the Romanian consumers prefer to access them directly from the store (using info-kiosk), to the detriment of accessing with mobile devices (phone / tablet) or from the personal computer.

Table 4: Intention to buy fish and fish products

Criteria	**Composite Priority**	**Rank**
Availability of information on the quality of fishery products	21.794	1
Availability of an adequate labeling	21.655	2
Accessing information on the quality of fisheries products (traceability) directly from the store (using info-kiosk)	20.504	3
Accessing information on the quality of fisheries products (traceability) using mobile devices (phone / tablet)	17.950	5
Accessing information on the quality of fisheries products (traceability) using a personal computer	18.096	4

Conclusions

Most of Romanian consumers preferred to purchase fresh or refrigerated fish and fresh fish rather than frozen or processed, preference placing them in the general trends of consumer preferences registered in the European Union, Turkey and China. The results of the survey show consumers are aware about the fish products safety including quality and the necessity of getting safety knowledge and they got a risk perception associated with fish products. Also, due to the interest in safety and quality, among the Romanian consumers of fish and fish products there is concern for accessing the information related to the quality of fisheries products (traceability) directly from the place of purchase, which is mostly the supermarket/hypermarket.

In conclusion, because was used a sample of consumers from all the Romania's territory, with a large range of age, gender, job category, level of education, this survey provides a chance to understand consumers' awareness to the quality and safety of fish products in Romania.

Abstract

Marketing communication and marketing are influenced by their environment, especially social development and development of informational technologies. To anticipate and meet the needs of current and potential consumers, enterprises must be able to reach specific target segments through selected marketing communication tools. Today, thanks to the unlimited possibilities of the Internet and information technology companies have new opportunities in the sale, distribution, and especially in communication with its customers. The aim of this paper is to identify and highlight the effect of selected trends in marketing and marketing communications to consumers' buying behaviour.

Keywords: advertisement, consumer, promotion, purchase behaviour.

Introduction

The communication tools must be used appropriately to suit the context of the markets being served, different customer needs and the firms' objectives. Media availability, cultural and legislation differences and the nature of the products and services being marketed will influence the communications strategy decisions and choice of tools. Customer perceptions can be damaged by poor communications management within the firm and by external factors over which the organization may have no control. The international firm must concentrate on communicating consistency in its image, standards and values to a diverse range of stakeholders as well as making its direct appeal to existing and potential customers. It must also integrate the traditional communications with online communications to further develop interactive, one-to-one customer relationships (Doole, Lowe, 2012). Integrated communications are the integration of formerly specialized communications functions into on organizational system that conveys a consistent set of messages to all target audiences. Integrated marketing and corporate communications manage each point of contact between the consumer or other target groups and the product or the organisation. Companies evolve only gradually to a truly integrated communications system. This slow evolution is caused by a number of important barriers to integration, such as the functional specialization in companies, existing structures, the lack of internal communications and the perceived complexity of planning and co-ordination. In integrated communications many instruments are used. They are embedded in a communications plan that has to be integrated in the strategic marketing plan (De Pelsmacker et al., 2013).

Literature review

Several authors like Kotler and Keller (2013), Kotler and Armstrong (2004), Štefko et al. (2015), Štefko and Krajňák (2013), Bačík and Fedorko (2015) indicate that the marketing communication means on the one hand to inform, to acquaint with product, explain their features, highlighting their benefits, quality, worthy, utility, and use the other hand to know and hear, receive suggestions and demands of consumers and to respond to them. Marketing communication is an indispensable part of

today's modern marketing. This requires more than just produce a good product, attractive to measure it or make the target customers. Enterprises have to communicate with consumers, and it can no longer be left to chance.

So what is the essence of marketing communications? To inform, to acquaint customers with the products they use properties, application areas and so on, but also to know them and listen to learn about their requirements and of course, appropriate responses (Bartáková et al., 2007). Marketing communication is one of the most visible and most discussed marketing tool with a growing impact on society and business. Customers and business managers are exposed to advertising; they use various forms of sales promotion, attending trade fairs, exhibitions, purchase of a certain well-known brand and so on. These activities affect the purchasing behaviour towards the promotion of sales of a product. Marketing communication includes all the tools through which the company communicates with the target customer groups to increase interest in the products or their public image (Cibáková, Bartáková, 2007).

In today's period, which is accompanied by the economic upturn, the market requires alternative solutions for maintaining business conditions. Cash and material flows are carefully guarded. Both parties - the seller and buyer are suddenly vigilant and cautious in all spheres of business. This trend has had to adapt to the other sales support activities. The solution is a new alternative, non-traditional forms of promotion (Lelková, Lorincová, 2015; Gburová et al., 2015). When talking about standard advertising we based on the theory that advertising is any paid, non-personal communications through various media by and identified brand or company. It is one of the most visible tools of the communications mix. Advertising campaign development consists of a number or stages. Firstly, advertising strategy has to be decided on: who are the target groups of the campaign, what are the objectives, and what messages are going to be conveyed? At the very core of the advertising process is the development of a creative idea. Companies have to write a creative brief before the advertising agency can start to do its job. Creativity is hard to describe, but bringing the message in an original, novel and appealing way comes close. Emotional appeals, on the other hand, contain information cues such as price (De Pelsmacker et al., 2013). Experts in advertising are betting on the fact that the internet is the main information and entertainment centre for people and the right through it they try to reach the target groups. The proportion of Internet advertising has recently seen a substantial increase, in contrast to other media, that cannot tell the same. When we consider the fact that radio to the took about eighty years unless it affected population on a large scale, television needed thirteen years afterwards, but internet needed just four years, which is a fraction of the time of other media. Taking into account the social networks such as Facebook or Twitter, the rate at which they spread to awareness among people is striking.

In a situation of growing immunity of consumers towards traditional advertising organisations tried to search for new forms how to better and more effectively reach target audiences. Such forms include for example product placement, buzz marketing, guerrilla, viral and mobile (viral) communication, or even word of mouth (Přikrylová, Jahodová, 2010). Advertisement belongs to the most important communication tools of businesses that are able to influence the purchasing behaviour of consumers (Lelková, Lorincová, 2015). At present its influence on successful management of enterprises is increasingly apparent. As everything also the advertising has its disadvantages, but they are not fully comparable with the benefits offered. The basis of success in creating of advertising is the knowledge of company analysis, its product, market, while measuring the effect of the communication, which aims to determine whether advertising successfully delivered messages to the targeted customers. For the advertisement it is spent lots of money because it is a tool that raises the most public debates. The most important step in the advertisement is the transformation of creative ideas, where it is necessary to pay close attention to the selection of appropriate techniques to preserve the effectiveness of advertising (Pelsmacker et al., 2003).

Methods and Methodology

The goal was to identify the effect of selected trends in marketing to the purchasing behaviour of Slovak consumers. The object of research was consumers living in the Slovak Republic. The sample was obtained at the choice of easy accessibility.

To achieve the aim of research, the following hypotheses were set:
- We assume that there are statistically significant differences in knowledge of trends in marketing depending on the respondent's education.
- We assume that there are significant differences in the preferred purchase via Internet depending on the age of respondents.
- We assume that there are statistically significant differences in the impact of advertising on consumer buying behaviour, depending on the gender of the respondent.

Respondents (consumers) responded to a questionnaire´s closed questions. Primary data obtained from questionnaire survey were later processed in a statistical program Statistica. In confirming or rejecting the established hypotheses it was used the method of Spearman's rank correlation coefficient and chi-square test.

Results and discussion

Age of respondents was considered to be an important factor, as a result of subsequent confirmation or rejection of set hypothesis. Age representation of respondents ranged from 17 to 37 years with average of 22 years. Ages categories involved in completing the questionnaire divided into three groups:

- up to 20 years
- 21-25 years
- over 25 years.

Research shows that the most represented was the age group of 21-25 years, which created 61.6% of total respondents. The second largest group was the age group up to 20 years, which had 30.3% representation. The lowest representation had the age group of over 25 years, where 14 respondents were represented what amounted to the equivalent of 7.6%. Within other identification questions it was investigated the highest level of education of the respondents. The graph below shows that the highest level of education ranged from basic education (9%) to University education. degree (6%), with most numerous secondary with GCSE (54%) and university first degree (30%). The lowest representation had Secondary schools (1%). At the beginning the research was focused to determination which factors are the most significant limits for consumers' purchasing. At this point of the research participants had a choice of several responses - low salaries, have a high price, unemployment, no factors and low price. On this question, there were added the possible answers and the possibility of others, where the respondent could enter another factor that restricts it when buying. The largest representation in the responses was the high price of 71%, which represents 131 respondents followed by low pay conditions (11%). No option checked only 15 respondents. Other options have been identified only in very few cases.

Within next question it was investigated whether the respondents sometimes met with the notion of new trends in marketing communications and marketing. The majority of survey respondents indicated a positive response (33%). Partly positive response chose 49 respondents (26%). The third option was the most commonly which corresponded to answer rather not. Only 13% of respondents did not know answer whether they ever encountered with this concept and 4% of respondents have never met with this notion. Since the new trends in marketing in the territory of the Slovak Republic are used not so much or not at all, the participants may not be aware that the promotion of what they see or have seen in the past include new trends in marketing.

The first hypothesis was verified by two questions. In the first one with identify character, where we asked for the highest level of education. In the other where we investigated whether the respondents have had contact with the notion of new trends in marketing. The following Table 1 shows us the distribution of respondents' answers up to different backgrounds.

Table 1: Evaluation of Hypothesis 1

			Have you ever heard of the concept of the new trends in marketing?					Total
			Yes	Probably yes	Don´t know	Probably no	No	
Education level	Primary school	n	3	7	4	3	0	17
		%	17,60%	41,20%	23,50%	17,60%	0,00%	100,00%
	Secondary school without graduation	n	0	0	0	2	0	2
		%	0,00%	0,00%	0,00%	100,00%	0,00%	100,00%
	Secondary school with graduation	n	25	26	13	30	5	99
		%	25,30%	26,30%	13,10%	30,30%	5,10%	100,00%
	University education (Bachelor)	n	28	14	7	6	0	55
		%	50,90%	25,50%	12,70%	10,90%	0,00%	100,00%
	University education (Master)	n	5	1	0	3	2	11
		%	45,50%	9,10%	0,00%	27,30%	18,20%	100,00%
Total		n	61	48	24	44	7	184
		%	33,20%	26,10%	13,00%	23,90%	3,80%	100,00%

Source: own processing

The hypothesis was verified by Spearman´s correlation coefficient, which value was -0.222, so weak negative relationship, which, however, was considered to be statistically significant ($p = 0.002$). The pattern is clear that respondents with higher education reported more frequent meetings with the concept of new trends in marketing and we confirmed the hypothesis.

The Internet is used to develop existing markets through enabling and additional communications and or sales channel with potential customers. It can be used to develop new international markets with a reduced need for new sales offices and agents. Companies can provide new services and possibly products using the Internet. Digital marketing can support the full range of marketing functions and in doing so can help reduce costs, facilitate communication within and between organisations improve customer service (Chaffey, Chadwick, 2012). Hypothesis 2, verifies if there are differences in the preferred purchase on the internet according to age. The distribution of answers of respondents, divided by age into three groups is shown in Table 2.

Table 2 : Evaluation of Hypothesis 2

			Do you buy products or services online?					Total
			Yes	Probably yes	Don´t know	Probably no	No	
Age	Up to 20	n	17	25	1	13	0	56
		%	30,40%	44,60%	1,80%	23,20%	0,00%	100,00%
	21-25	n	38	52	1	20	3	114
		%	33,30%	45,60%	0,90%	17,50%	2,60%	100,00%
	over 25	n	3	7	0	3	1	14
		%	21,40%	50,00%	0,00%	21,40%	7,10%	100,00%
Total		n	58	84	2	36	4	184
		%	31,50%	45,70%	1,10%	19,60%	2,20%	100,00%

Source: own processing

According to the response rate it can be seen that the biggest difference between the compared age groups was the preference options certainly yes. A lowest purchase of products over the internet was

seen at example of oldest respondents (12% opposed to the middle age group). Overall, the chi-square test did not show evaluation of statistically significant difference (chi-square = 4.677, p = 0.791), so the hypothesis is not confirmed, as compared age groups differ.

Within the last hypothesis we verified whether advertising sometimes caused to consumers rise to the immediate purchase of certain goods or services. Subsequent identification issue was the question of the gender of the respondents.

Table 3 : Evaluation of Hypothesis 3

			Have advertising cause you initiative for immediate purchase certain goods or services?					Total
			Yes	Probably yes	Don´t know	Probably no	No	
gender	men	n	3	19	7	20	11	60
		%	5,00%	31,70%	11,70%	33,30%	18,30%	100,00%
	woman	n	22	49	15	30	9	125
		%	17,60%	39,20%	12,00%	24,00%	7,20%	100,00%
total		n	25	68	22	50	20	185
		%	13,50%	36,80%	11,90%	27,00%	10,80%	100,00%

Source: own processing

The hypothesis was verified by chi-square test of independence criteria, in Table 3 is presented the distribution of the responses in both men and women. The table shows that, men are more inclined towards a negative response. Women answer more positively. Women succumbed immediate impulse to purchase. The difference was considered to be statistically significant (chi-square = 11.347, p = 0.023) and on the basis of it given hypothesis was confirmed.

Conclusion

The paper aimed to point to the impact of new trends in marketing and marketing communications to consumers' buying behaviour, where investigated the information and theoretical knowledge about new trends in marketing and so wanted to raise public awareness of these trends in marketing. Based on the questionnaire survey, subsequent analysis and verification of set hypotheses, it was found out the following facts. The impact of new tools in marketing in this survey influenced mainly the female gender, which may be due to better involvement in purchases. Our analysis also found out that respondents with higher completed education know, respectively, with the concept of the new trends in marketing they have met, but this does not guarantee their utility and application in practice.

This article is one of the partial outputs under the scientific research grant VEGA 1/0857/15 “Research of economically significant factors of perception of reputation and its dominant contexts in relation to the success in the processes of e-commerce and e-marketing on the Slovak Virtual Market.”

Abstract

This article covers the issue of the quick profitability assessment method for the transport orders acquired from the transport exchange market. For this purpose two algorithms were suggested that were developed in order to increase the pace of the decision making process. The first algorithm ” geo-position” makes the time shorter for the information to be retrieved from a digital map and the second one “improvement“ algorithm selects the transport orders on the basis of the optimal costs with a short time delay.

Keywords: transport exchange market, transport orders profitability, optimal algorithm

1. Introduction

Permanent development of the transport exchange markets has brought about many changes based on the ongoing searches for the long term transport contracts or orders for the transport companies. This process in which the transport orders are acquired and then analyzed taking into account the calculations of the previous orders is made to finalize the process by preparing an offer that is determined by the time that is; the time of the decision making process.

Examining only the analysis of the order as such it was concluded that previously it was necessary to determine precisely the loading / unloading location, evaluate the number o similar orders, (that is; the distance between the loading place and the actual route) predict the number of the areas so that the distance to the location was the shortest possible as well as to check many other parameters affecting the profitability and the cost involved. The time to prepare an offer involved many people, which made it long before the actual order was proceeded This ,on the other hand, affected the profitability and the availability of the transport means due to the delays in decision making process. Presently it can be observed that the search for transport orders is more dynamic thanks to the operation of the transport exchange market which has become a platform for well established and new companies to compete on the market. That is why the transport exchange market is often called a lottery where it is possible to acquire profitable orders as well as to cover the costs of the fleet maintenance.

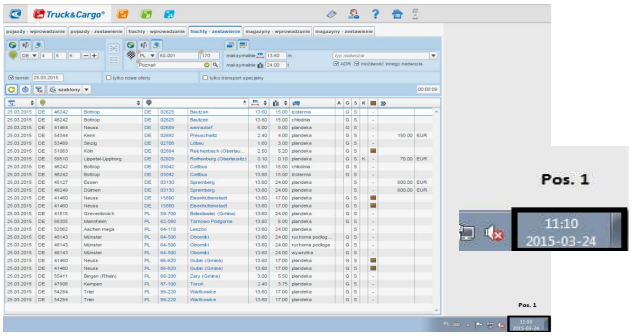
It is worth considering the question what are the profits that can be gained by using a transport exchange market ? Analyzing the offers we can conclude that the transport exchange market is an efficient tool for optimizing the logistics. It does not mean that the exchange market would tell the user how to reduce the costs or which criteria should be chosen for selecting the best route. In this case it turns out that the work of the experience transport operators proves to be crucial as far as the efficiency is concerned while the transport exchange market makes an excellent tool to determine free transport means and the loads available. This information nowadays is a key to success in logistic business. It lets the companies save time as the communication is so developed that it enables them to be in touch with a great many contractors and have an access to a great amount of cargo and the transport space availability, which can be effectively organized and managed by using computerized systems.

There is no doubt that in 21th century it is more and more difficult to imagine a modern transport system without the logistic exchange market however, the efficiency of transport mainly depends on the application of the IT tools which are used to plan, coordinate, store and optimize the proceedings due to the application of proper algorithms[1]. Summing up we can say that the transport exchange market is a source of information that is further proceeded by the computer system, making it so efficient and profitable.

2. Acquiring the profitable orders from the transport exchange market – case study

Despite the fact that the contemporary transport exchange markets offer their customers modern computer based tools which, as it is said , "make the business more efficient and transparent" they unfortunately limit their functionality to the presentation of more and more loads and their control during the transportation. Consequently, the functionality such as; the route costs calculation or the monitoring of the vehicles with the "tele-matic" system suggesting the operation work on one platform, concerns only the situation referring to the load that has been put on the transport exchange market and its transportation. The way in which the transport business operates makes us consider other aspects (not included in the offers) that affect the profitability of a particular order. It mainly concerns the distance to the loading location (that is empty run distance) as well as the difference in costs depending on the company. As it happens very rarely that the transport offer appears in the location where the company has the vehicle available. It is also impossible to determine the same distance costs for every company using transport exchange market. Therefore the key factor for the transport operators is to evaluate the profitability of a given order in a very short time.

It is worth pointing out here that the profitability evaluation makes a complicated process and is related to the additional analysis of the parameters such as; the area of loading (industrial areas of Europe give the guarantee of large quantity loads ,which means that the probability of finding the next order is very high), the distance to be covered (the longer distance the higher the price and lower costs resulting from the distance to the loading location), the time of the transportation (short term motivates the suppliers to put up the price), price (the ability to calculate the costs involved to reach the loading location and the transportation to the unloading spot, which supports the calculation of the whole order to be proceeded. The operation proceedings of the transport operators and the dynamically changing orders in the transport exchange market are illustrated in the pictures in sequence 1, 2, 3.

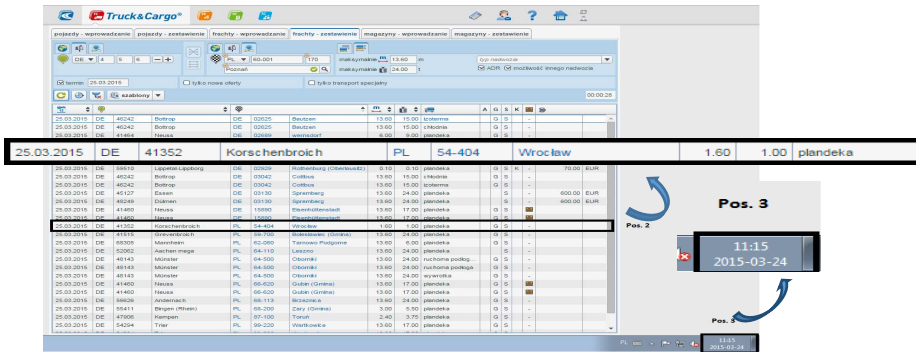


Picture 1: Screen shot of the transport exchange market TimoCom –11.10 am.

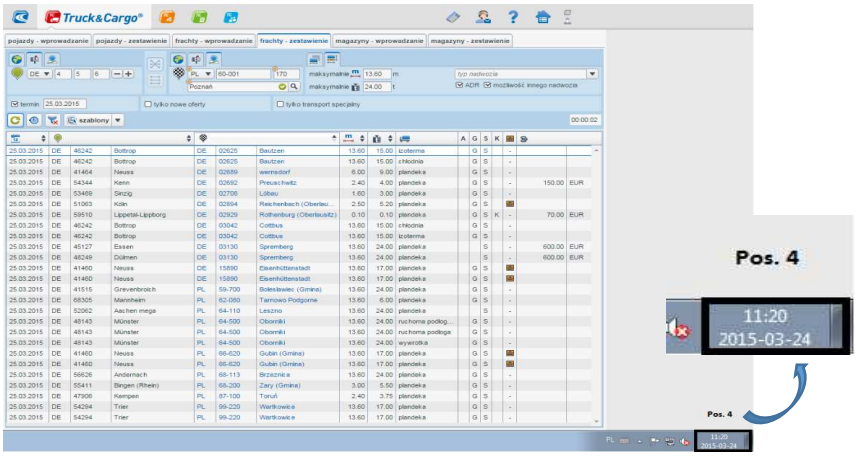
[1] Chen Shi-Jie, Mazur Ł. and Sąsiadek M. (2013) 'Project task flow optimisation and departmental flow analysis using design structure matrix and genetic', *International Journal of Logistics Systems and Management*, , Vol. 15 (1), 68—92..

In Picture.1 one of the biggest transport exchange market was shown. The observation of the incoming orders started at 11.10 am (Picture. 1). In this time there was no interesting transport offer. Picture. 2 shows the screen shot of the same transport Exchange market but only 5 minutes later, that is; at 11:15 am 15am (Picture 2, pos 3). At this time one offer appeared for the route; Korschenbroich (Germany) – Wroclaw (Poland). The offer did not include the price so it was negotiable. The offer can be determined by the following operations to be carried out; checking for available vehicles, calculating the distance to the loading location, calculating the transportation distance, calculating the costs , determining the income distribution and negotiating with the customer.

This means that one of the users decided to take this order so all the operation related to the decision making process can't have lasted more than 10 minutes. This situation shows a typical work of the transport operator who without proper tools assisting his decision making process is forced to take a risk or trust his or her experience. In this case the success rate is conditioned by luck, experience and a random calculation not a reliable assessment and planned operation procedures.



Picture 2: Screen shot of the transport exchange market –11.15 am.



Picture 3: Screen shot of the transport exchange market – 11.20 am.

The experience of the operator mainly refers to his or her knowledge of the digital map and the ability to assess the distance between the loading / unloading locations . On the other hand the evaluation of the costs is based on defining the costs for the vehicle to reach the loading location (unloaded run) and the transportation costs (loaded run) This differentiation plays an important role because of the value of the estimated costs and assigning them to the transportation distance as a whole.

The authors of this article carried out the analysis of the operational costs of the company with whom they cooperate daily. On this basis the average annual costs of the company for the distance to the loading location was determined by summing up the permanent and changeable costs including the mark-up that the company imposed when the vehicle was reaching the loading location. Next, dividing value by the summarised number of kilometres covered annually[2]. Analogically, the average annual cost for one kilometre was calculated. The results for the company that has the transport means ranging from 150 – 200 vehicles with trailers amounted to 0,75 EUR for one kilometre for the distance to the loading location and 0,85 for the transportation of the load. Using similar calculations the profits that is generated by the transport exchange market orders was determined. It is worth pointing out here that the companies tend to hide both the number of kilometres and the costs. In most cases the customers of the transport exchange market are interested only in the value of the order and not in the number of the kilometres to be covered to reach the loading location and proceed the transportation. To analyse the income and the costs of the kilometre the "Frachteo" internet portal was used[3]. On the basis of the 2500 quotes of the offered price in relation to the different destinations offered by the portal it was determined that the particular income ranges from 0,9 EUR to 1,3 EUR per one kilometre. The tests started in January 2015 and have been carried out till present. The difference in incomes in relation to the value of one kilometre is significant with results mainly from the evaluation of the profitability of the company taken annually. Most of the small and medium companies tend to analyse so called "big numbers" that is; the values collected from a long period of time, mostly covering one year. In this case the analysis concerns; the number of the kilometres covered with and without the load for all the vehicles in service and the costs involved as well as the profits generated .

On the basis of this data the evaluation economical instruments were defined in order for the operators to make decisions during their work on the transport exchange market.

In conclusion the case study covering the route Korschenbroich (Germany) – Wroclaw (Poland) (Picture. 2), would show which operation the operator should carry out

a) Determine the number of kilometres,
b) Assign the closest vehicle possible, which on 25.03.2015 can reach the loading destination in Korschenbroich (Germany),
c) Determine the number of kilometres to be covered to the loading location,
d) Check if in the nearest term 26.03.2015 there will be a load to be taken from the city Wroclaw (Poland) because it makes an unloading location, which would greatly limit the costs of the next order,
e) negotiate and determine the price with the order supplier

As mentioned before, the transport operator has only 10 minutes to make a decision so he or she can make many mistakes The best example is the calculation illustrated in the Table 1 and 2. In the calculations the vehicle must reach Holland (different unloading locations) then move to Germany that is to the loading place only to drive on to Poland. The operator in this case must carry out all the operations mentioned before.

[2] Woźniak W., Jakubowski J. (2015), 'The choice of the cost calculation concept for the mass production during the implementation of the non-standard orders', 26th IBIMA Conference, 2015, Madrit, p.2364-2371.

Table 1 : Order profitability calculation - destination option A

Own calculation - destination option A		Kilometres	Costs	Cost value
Destination	Rotterdam (Holland)	210,00	€ 0,75	€ 157,50
	Korschenbroich (Germany)			
Transportation	Korschenbroich (Germany)	860,00	€ 0,85	€ 731,00
	Wroclaw (Poland)			
Total		1 070,00		€ 888,50
Calculation for the customer		Kilometres	Costs	Order proceeding value
Transportation	Korschenbroich (Germany)	860,00	€ 1,00	€ 860,00
	Wrocław (Poland)			
Order profitability analysis				**-€ 28,50**

Table 2: Order profitability calculation - destination option B

Own calculation - destination option B		Kilmetres	Costs	Cost value
Destination	Eindhoven (Holland)	100,00	€ 0,75	€ 75,00
	Korschenbroich (Germany)			
Transportation	Korschenbroich (Germany)	860,00	€ 0,85	€ 731,00
	Wrocław (Poland)			
Total		960,00		€ 806,00
Calculation for the customer		Kilometres	Costs	Order proceeding value
Transportation	Korschenbroich (Germany)	860,00	€ 1,00	€ 860,00
	Wrocław (Poland)			
Order profitability analysis				**€ 54,00**

If this route were to be covered because of the instability of the transport orders in the selected directions (for example the case of increasing number of the orders towards Germany and limited ones towards Poland) the profitability will always be achieved for such an order even if its profitability as such will be negative.

3. Methodology and decision making support tools in relation to the selection of the profitable transport orders.

A short time and the lack of possibility to evaluate the business situation at the moment the decision is to be made, which makes it a complicated task to choose an optimal selection in the light of the profitability, greatly affecting the development of the company.

Despite the fact that these tools are widely used and are offered by the transport exchange portals in addition to the company's own transport management systems the speed, at which the clues as far as

the profitability is concerned, is still very limited and in most of the cases the problem lays in delayed proceeding time and the digital map reaction as well as the assignment of an optimal solution via the use of the computerised transport management systems.

Analysing particular elements of the operations that are done by the transport operator during the process of the orders acquisition from the transport exchange market the following method was suggested, which may significantly shorten this process. In the Table 3 seven steps were presented giving a full picture of the transport operator work. The yellow colour was used to indicate these steps which can be improved by using the suggested tools.

In this method the operator is still using his or her experience and skills in order to plan and acquire the orders from the transport exchange market. This can be achieved thanks to the 2 alternative methods illustrated in step 2 and 5 (yellow colour). In the first case it is suggested using the application of the algorithm which takes the graphic coordinates on their basis assigning the initial geographical position for the vehicle (the location of the previous upload location or actual position and the geographical position of the uploading resulting from a given order. Next, the distance is calculated (in kilometres) in a straight line between the defined coordinates points. In the next step, the algorithm defines the time needed to reach the destination in a straight line by using the statistical data and the average speed for the vehicle in a given region (similar to the digital map).

The value that has been retrieved is then compared to the work schedule of the driver (working hours according to the road and safety regulations) In this way, having determined the working time and the number of the kilometres the algorithm excludes these orders that do not meet the basic criteria.

Table 3 : Suggestion for the selection method of the profitable transport orders

Steps	Operations	Tools
Step 1	Assigning adjacent points: - max distance to the destination in kilometres, - the cost of an order, - the cost of the transportation, - the value of an income and other values.	Statistical data analysis from previous orders via TMS or other computer based tools.
Step 2	Uploading orders from the exchange market.	The application of the available computer based tools.
Step 3	.Analysis of the available vehicles and the loading destinations derived from the exchange market.	The application of the digital map functions
		Own suggestion: the method and the computer based tools in order to develop a matrix of the distance in relation to a geographical position – the "geo-position" algorithm
Step 4	Defining the orders (based on data from step 3) which are feasible to proceed	The application of the available computer based tools.
Step 5	Defining the optimal solution for the shortest distance to the uploading location as well as the lowest costs involved.	The application of the optimisers used in TSM or on the basis of own tools
		Own suggestion – the method of profitable orders selection based on the optimising algorithm "improvement algorithm"
Step 6	Selected order price quotation and negotiations,	Communication with a supplier
Step 7	The order profitability calculation	Computer based tools application (own, TMS or other tools)

This solution is called the algorithm of geographical position which makes up a first matrix of the available transport means and the acceptance of the orders with the parameters such as the distance, time to reach the destination and the time of the driver work schedule (step 4). All the orders that are accepted by the algorithm go on to the next step for which a digital map is used as a standard.. At this stage we can observe some time savings in the analyses of all the interrelations based on the vehicles available and their relocation on the digital map.

In the next step , as an alternative option for the tools used in modern TMS systems it was suggested using our own algorithm that is the algorithm of "improvement"[4]. This algorithm can be characterised by a short time complexity, namely; the time of the information access in relation to the most common and widely used optimising algorithms of TMS systems which includes the transport algorithm and in this specific case – the "Hungarian" algorithm[5].

The algorithm of „improvement" was used to optimise the possessed orders in relation to the lowest cost of the order proceeding. The time for the calculation to be completed for 40 vehicles with the transport exchange market orders ranging from 40 – 80 can be seen in Table 4. Even with the optimisation of the 80 orders retrieved from the exchange market the time did not exceeded 1 minute.

Table 4:Time complexity for the "improvement" algorithm

Number of ordeers	Unit	Result time complexity for the "improvement" algorithm	
		Min. time	Max. time
40	**µs**	13 091 956	16 625 676
40	**minutes**	0,218	0,277
45	**µs**	15 780 079	17 999 959
45	**minutes**	0,263	0,299
50	**µs**	18 779 995	21 190 365
50	**minutes**	0,312	0,353
55	**µs**	21 499 997	25 686 380
55	**minutes**	0,358	0,428
60	**µs**	23 664 384	27 950 021
60	**minutes**	0,394	0,465
65	**µs**	27 430 071	35 533 736
65	**minutes**	0,457	**0,592**
70	**µs**	31 120 128	34 846 478
70	**minutes**	0,518	**0,58**
75	**µs**	34 160 014	38 204 563
75	**minutes**	0,569	**0,636**
80	**µs**	38 669 992	45 396 568
80	**minutes**	0,644	**0,756**

[4] Woźniak W., Wojnarowski T. (2015), 'A Method for the rapid Selection of profitable Transport Offers within the Freight Exchange Market', 25th IBIMA Conference, 2015, Amsterdam, p. 2073 – 2085.
[5] Ibidem

As a result of the 'improvement" algorithm execution the result was achieved in which All the 40 available vehicles were assigned to 40 different orders derived from the set of 80 orders to be considered. The parameter for the algorithm was the lowest cost. Table 5 illustrates the fragment of the sorted table. Consequently, the matrix is filled with the values of the costs and their proceedings from the step 3 ,which is influenced by both the distance to the loading location and the load transportation according to the rates examined and evaluated in part 2.

The data that has been generated via the „improvement" algorithm indicate a real number of kilometres which is to be proceeded in a given order and the costs include additionally the distance to the loading location. Consequently, the analysis of the kilometres from the data is not adequate to the pre-defined costs (for example; comparing the position 1 and the position 2 in the Table 5) This , on the other hand, might be essential tool for the operator to increase the profitability of the orders due to his or her knowledge about the distance (number of kilometres and duration) and the distance to the loading location.

Therefore when the costs of the order is available the number of kilometres to be covered and the allocation of the income then the operator, can start negotiating and defining the price. At this stage the profitability of the orders depends on the negotiations only.

Table 5 : Example results for the optimising algorithm of "improvements"

L.p.	Vehicle ID in data base	Unloading location (start point for the destination)	Loading location (start point for the transportation)	Unloading location (endpoint for the transportation)	Order cost proceeding	Kilometres from the order
1.	1	COTTBUS	IŁOWA	FOERITZ	386	389
2.	26	ARNHEM	HURTH	MARMOUTIER	406	320
3.	29	COTTBUS	IŁOWA	KREMSMUNSTER	472	490
4.	8	KLATOVY	LITVINOV	ARETSRIED	491	440
5.	23	CHARLEROI	LAAKDAL	DORNSTETTEN	516	528
6.	6	KLATOVY	NERATOVICE	TURKHEIM	559	520
7.	22	STAROGARD	JANIKOWO	WEIHERHAMMER	768	745
8.	4	ORMOŻ	PISCHELSDORF	OSTROŁĘKA	811	820
9.	39	ZGIERZ	WŁOCŁAWEK	SATERLAND	848	906
10.	33	ROTTERDAM	FELUY	BEESKOW	863	854

This kind of the acceleration of the operator's work by using the "geo-position" and "improvement" algorithm in relation to defining of the costs and profitability enables us to make decisions in the time shorter than 10 minutes for a selected group of transport orders. The method suggested here and the application of the solutions discussed makes an alternative option for expensive and limited in its functionality solutions that are used in the transport systems operating on the transport exchange market.

4. Conclusion

The phenomenon of the transport exchange market is strictly connected with the operational improvements in the area of transport processes and the establishing of international contacts to access the loads directly. Because of this the costs of so called unloaded runs are greatly eliminated enabling bigger profits to be achieved. It is estimated that 90 % of the transport companies make use of different transport exchange markets. The idea that the transport exchange is only a kind of virtual advertising has been abandoned long time ago since their functionality has proved to be very efficient in relation to the work proceedings and the data analysis. Unfortunately the tools that are often used do not serve the function of the TMS systems, which means that a great amount of time is lost for the integration of data and retrieving the information. In fact all the tools that are made to accelerate the work on the transport exchange market such as the " improvement' or "geo-position" algorithm can be used as an effective tool to compete for the profitable orders on the dynamically evolving transport market.

Abstract

Commercialising of the research product has now become one of the critical issues towards achieving innovative nation and generating wealth creation especially relevant for Malaysia. One of the elements of research products commercialisation is promoting a strong and an effective collaboration between university and industry. They have been a lot of attempts and iniatives in bridging the two worlds, however, the collaboration is not strategically promoted and is still less satisfactory. Thus, this paper aims to review factors for an effective collaboration between university and industry towards commercialising research products. For the purpose of the study, interviews were conducted with six academic researchers who have experienced in collaborating with the industry. Drawn from their insights and experiences, this study identified factors with respect to the role of the university, research product and academic researcher. These factors are important for academic researchers and their industry partners to develop and plan strategically for an effective, strategic and sustainable collaboration in commercialising research products.

Keywords: Research product commercialisation, Collaboration, University and industry, Academic researcher

Introduction

Commercialisation of the research product has now become a critical issue in the university. This process involves translating knowledge from research into a new and improved products and services (Isabelle, 2004). For this reason, the role and function of the university have expanded from traditional teaching and learning to include commercialisation activities. The production of new and improved products from the university have pave the way for new opportunity for university to enjoy a more commercialised status, and some may refer as "entrepreneurial university" (Ramli et al, 2013; Karlsson, 2004; D'Este and Perkmann, 2010). This situation has also encouraged university to become an independent body to create its own income (Ramli et al, 2013; Howitt, 2013; Han and Heshmati, 2013). It has also been emphasised that universities are treated as an engine of wealth creation through commercialisations tools (Markman et al., 2008. However, it is interesting to note that commercialisation of research product particularly in the university is still new and less encouraging in Malaysia. Furthermore, there are also little findings to support for commercialisation activities in Malaysia. This is because commercialisation is required a long and complex process. Furthermore, it has been stated that since universities are still focusing on traditional teaching and researching, commercialisation is still considered as a long way to go (Galushko and Sagynbekov, 2014). In fact, publication has become priority among academics (Behboudi, Jalili and Mousakhani, 2011) to fulfil their key performance index or to get promoted. The worst scenario is that some academics found that commercialisation has no relevance to them (Farsi, Moderessi and Zarea, 2011; Boadu and Metla, 2008) and some may think that commercialisation requires too time consuming (Aziz et al., 2013; Galushko and Sagynbekov, 2014; Yaakub et al., 2011).

There are many ways on how universities set their own strategies for commercialisation, and some have adopted internal, quasi-internal and externalisation approaches (Markman et al., 2008). They also engaged through research contract, consultation and joint research (D'Este and Perkmann, 2010). These strategies are important especially in identifying their novel intellectual property rights and their financial strategies to maximise the success (Siegal and Wright, 2007). Various programs and inititiaves have been put forward by the university to encourage collaboration towards the effective research product commercialisation. These programs include for example incubators, education and

networking programs (Karlsson, 2004) and the establishment of the technology transfer office (Teng, 2010); Siegal, 2013) to facilitate the collaboration process. University will also adopt commercialisation policy and issues related to academic rights, ownership rights, sharing of the profit etc (Ab Aziz, Harris and Norhashim, 2011; Ramli, et al., 2013). Research management centre or technology transfer office plays an important role to coordinate and facilitate the commercialisation activities in the university (Sastry et al., 2007; Jensen and Thursby, 2001). Apart from that, collaboration between university and other agencies including research centres and industries are one of the strategic approaches to encourage for research product commercialisation (Siegal and Wright, 2007; Ramli and Zainol, 2013). To foster an effective collaborative culture between university and industry, there are certain ways to be employed where; (a) industry financially supports university and academics are free to decide their research as agreed; (b) industry involves as part of the members but does not involve in research activities; (c) industry orders specific types of research to university, and they have more rights on the result from the research; and (d) industry and university equally involve in the research and they gain equal benefit from such collaboration (Lind, Styhre and Aaboen, 2013). However to ensure that collaborative agreement is a success, there are certain criteria which industry expected from the university, and vise versa. It is claimed that university should produce research product that meet the market requirement and consider the technological trend in the industry (Yusuf, 2006).

Since commercialisation involves a complex process, there are challenges and gaps that need to be addressed. Although many initiatives have been put forward by the government, nevertheless there are challenges as regards lack of funding, lack of collaboration between academic and industry, lack of emphasis on innovation and lack of human capital (Govindaraju, 2010). Furthermore, due to tacit nature of knowledge, there was a problem to collaborate between academic and industry (Etzowitz, 1998). Lack of expertise in the relevant field and lack of expertise in management skills are also identified as challenges for successfully commercialising research products (San, Narayanasamy and Ahmad Dahlan, 2012). Lack of technology transfer office or research management centre's capabilities are identified as one of the challenges to facilitate, monitor and sustain the collaboration (Farsi, Moderessi and Zarea, 2011). It is said that this office or centre is still new and less experience in conducting commercialisation related activities (Yaakub, et al., 2011) and their personnel lack capabilities in marketing, technical and negotiation skills which lead to many research product remain uncommercialised (Farsi, Moderessi and Zarea, 2011). Another challenges is that reward and incentive systems are not properly granted to the academics to pursue for commercialisation. Furthermore, research product failed to meet the market demand and it lacked of competitive advantage (Farsi, Moderessi and Zarea, 2011) and research conducted in the university normally failed to give proper consideration to the industrial problems (Anbardan, 2013). Moreover, there are different motivations between university and industry; whereby academics prefer to share their knowledge, whilst industries try to keep the information secret from their rivals (Aziati, Hazana and Ping, 2014; Ramli and Zainol, 2013).

It was reported from the empirical study that there were factors that contribute to focus on the collaborative partnership between university and industry. A new program and project management was also found to be useful to reduce the gaps between both entities (Fernandes, et al, 2015). Adoption of this program and project management has emphasised on the structured objective setting, good progress monitoring and effective communication towards effective collaboration between university and industry (Fernandes et al, 2015). It was suggested however that this program and project management was not a "recipe" for all university-industry collaborative context, but a careful consideration need to be adjusted by a manager or management team to respond to a particular program requirements (Fernandes, et al, 2015). The study conducted on 142 firms in Konya found that the level of collaborating degree between university and industry was still not sufficient and there is a positive directed linear relationship between the frequency degree of collaborating with the university and number of employees in the institution which is necessary of being institutional (Sendogdu and Diken, 2013). Thus, the collaboration is often failed to be materialised in the institutional firms (Sendogdu and Diken, 2013). It was found in Chinese university and high technology industry that university and industry collaboration is established by various factors such R&D tendency, R&D risks, R&D promotion in terms of incentives (Riaz, 2013). It was also emphasised that there are significant output based on such collaboration including innovative

incentives, technological gains and sharing R&D costs (Fiaz, 2013). Similarly, it was viewed that collaboration between university and industry affected process innovation and product innovation is positively affected by the geographical area to a university but negatively affected by the amount of its production of knowledge (Maietta, 2015). For a successful commercial collaboration it was suggested for university and industry to adopt a long term strategic planning and a tactical approach for handling day-to-day operations (Liew, Tengku Shahdan and Lim, 2012). In Denmark, researchers experienced an institutional convergence to share the culture of knowledge sharing and effective communication for joint projects with industries, especially when they engaged social skills to bridge the perceived gaps (Bjerregaard, 2010).

Thus, this paper focuses on the determinant factors that lead to the effective collaboration between university and industry. This is because if collaboration between university and academic manages to tackle all issues and challenges, commercialisation will be treated as a success one (Karlsson, 2004). Furthermore, the important motivation behind the creation from the university is not only creating profits for the university per se, but in fact it should give impact to the society and nation as a whole.

Research Methodology

For commercialising research products, there are many factors to guarantee the success of commercialisation, and one of them is to collaborate between academic researcher and industry. Successful collaboration between academic and industry is significant to ensure that commercialisation of research product is reaching the market segment. However, this is not always be the case since there are many factors contributing to guarantee the success of collaboration between academics and industry partner. This paper addresses the following research questions:

(a) What are the determinant factors for a successful collaboration between academics and industry;

(b) What improvement can be made to ensure for an effective collaboration between academic and industry.

To answer this research question, this study employed a qualitative research using semi-structured interview questions. Six academic researchers have been purposely selected for the interview. They were chosen based on these criteria; (a) various and extensive experiences in technical and scientific background; extensive experiences in commercializing research products; (c) extensive experiences of collaborating with industry partner; and (d) represent the academics from the Malaysian public university. The six interviewees are identified and referred as DR, AN, SZ, LY, RZ and EN for the purpose of anonymity.

The interview questions were designed based on the structure developed by Patton (2002). This study adopted face-to-face semi-structured interviews with the six respondents. Each interviews session lasted from approximately 1 to 1 ½ hours. The researchers asked the permission to record the interviews and they were transcribed verbatim. All information gathered from interviews were analysed based on axial coding.

Findings and Discussion

Successful collaboration between academic and industry is significant to ensure that commercialisation of research product is reaching the market segment successfully. This study has identified and examined the main determinants for effective collaboration between academic researcher and industry partner, which can be categorised into three main aspects namely; (1) role and function of the university; (2 producing innovative research product and (3) competencies of academic researcher. This study recommends ways for improvement between academic researcher and industry towards a better and effective collaborative engagement and commercialisation of the research products.

Role and Function of the University

University plays significant role in bridging between academic researcher and industry partner. University supports may come in the form of the effective role and function of the research

management centre. This centre is dedicated to facilitate and monitor issues related to research and development (R&D), research products and commercialisation in the university. However, the role and functions are not only limited to these particular aspects only, but they are also providing platform for networking purposes between these two worlds. The significant role and function of the research management centre have been emphasised by three interviewees in this study. Interviewee DR stated that research management centre supported the collaboration by providing a team of experts and personnel to assist for collaboration. He said that:

"Good team is very important to support for such engagement, they are a team of accountants and good personnel who are able to deal with business related matters, and good public relation with outsiders". This was also agreed by interviewee SZ where he stated that *"the personnel help us [academic researcher] a lot in term of the agreement made in the form of MOU and MOA. They are also acted on behalf of academic researcher in terms of commercialisation activities and related matters, promotion and advertisement in supporting for collaboration"*. An interesting observation made by interviewee RZ where he said that *"research management centre tries to match whatever technology we have with the interested industry. After that, they make us meet with the industry"*.

Thus, various role and function in bringing closer link between academic researcher and industry partner provide a good platform towards successful research products commercialisation. Their active promotions of the potential research products in the university guarantee for effective engagement between these two parties.

In addition, sufficient funding is also found to be one determinant factor for an effective collaboration towards commercialising research products. This shows the seriousness from the part of the university towards encouraging for active and effective collaboration with the industry partner. Normally, at the early stage of commercialisation endeavour, it requires huge investment in producing mass of products and subsequently attracted the potential industry collaborator. Interviewee DR shared his thought on this when he said that:

"We started with pre-commercialisation, we have internal fund which are secured by hundred thousand. That hundred thousand I bought a second hand machine for the brick manufacturing. […] Even though it is old machine, at least it gives us some idea how the process work. So by using that machine, we are able to convince our partner".

Sufficient funding provided by the university helps academic researchers to attract and convince the potential industry to collaborate with them. This is equally true to small medium enterprises (SME) which expected to get financial assistance from the university in order for them to go for the mass production. This is further emphasised by interviewee DR where he stated that to convince the industry partner, the university must really committed and appreciated in achieving commercialisation stage.

In encouraging collaboration, university must play an active role in promoting academic research products. Promotions can be made formally, for example through scientific and engineering exhibitions, either at national or international level, conferences or any other scientific competition. This provides as a platform for academics to expand their networking with other researchers from different areas, and also with the potential industry collaborators, as emphasised by interviewees AN and SZ. Similarly, interviewee DR was also very lucky to meet his own industry partner through the scientific exhibition. According to him, he met influential people and this person was really impressed with his products, and this has become his introducer to the interested industry.

Promoting research products is one of the ways to facilitate the process of university-industry collaboration. Interviewee SZ stated that:

"It is not difficult to actually collaborate with industry. We just need to be actively promote our product […] have a very broad marketing. My media team from university is very good". Similarly, interviewee LY agreed that university has played its role in promoting his product to the potential industry collaborator. The active promotion that played by the university manage to advertise the research product to the outside world.

Research Products

Producing of innovative research products is the main determinant factor that contribute to the collaboration between academic and industry. Producing quality products with reasonable price manage to attract industry partner to effectively engage with the academics. The capability of product to offer a low price in the market is one of determinant to ensure the success engagement between both parties, academic researcher and industry partner. This study highlighted that three of the interviewees were able to produce a quality product at reasonable price. Interviewee DR shared his experience in comparing his product with another products and stated that:

"Customer has started asking because are we selling the brick at the price of 28 cent per piece which is similar price to a cement brick. Cement brick is not as good as this. And the quality is quite similar to clay brick. Clay brick is 45 cent per brick. But of course you see, that is just a small amount, just 28 cent. But then, when we talk about project for example, building like chancellery building. Chancellery building will use about 2million bricks. So it becomes big". Similarly, interviewee LY confidently claimed that "*my product is cheaper, stronger and lighter"* and this was also supported by interviewee EN where he added that:

"If the product is really good, really useful, and suitable with the price, I think it should be no problem".

Thus, quality but yet reasonable product enable to attract industry partner to collaborate for the business.

Creating and producing product that able to solve market problem is another way on how to attract the industry partner to collaborate with the academics. In order to meet the market demands, academic researchers need to find the problem in the market and try to solve them by offering their products to the potential industry. In this sense, industry partner will appreciate the efforts made by the academic researchers. Furthermore, this type of products guarantee that the products will have the potential consumer in the future. Furthermore, this type of product manage to benefit society as a whole, as observed and agreed by interviewee EN where he said that:

"It started from problem faced in the school. So we solved the problem. Thus, whether the project is big or not, it must be useful to the society. Otherwise, your product cannot be commercialised. For example let say I leave in a village and near to a river. Usually the electricity run off during the flood. What do I need? I need a clean generator. Because the existing one is smell and oily. If there is one generator using solar and green technology which I can put at my home, I will buy it even though the cost is high. It is a need. So back to basic, what is the need of our society? We need to do something new which people really need it".

On a similar note, interviewee DR also claimed that research product should benefit the society as a whole and manage to provide solution to a particular problem. Thus rather than focusing on their own key performances index (KPI), academic researchers are now have to consider the market needs of their research products. Producing a good research product alone does not guarantee that industry will attract to the products, but academic researcher must show that their products tap to the market needs and worth to the society.

Uniqueness of the research product is one criteria that industry partner is taken into account to collaborate with the university. Interviewee SZ shared his view on this by saying that his product has created a value-added that successfully attracted collaboration from the industry partner. He further stated that:

"This product is very high fibre, high shelflife, long lasting, and the vitamins and minerals maintain in there. […] I made it suitable to be commercialised and ensure the uniqueness of my product and availability of sources. I added value to existing product". Creating value-added product also was also agreed by interviewee LY where he has promoted the system that was very economic, sustainable and benefit to the user. The uniqueness of his product provides him a good platform to meet his potential industry partner.

Due to the tight budget, many industries prefer to accept market ready products rather than producing them. In other words, they prefer to consume the products rather than manufacture them. Industry partner is not willing to spend more in developing the product, but they expect to have a market-ready product. This market ready product will be easily and quickly entered into a market place. This is equally true since commercialisation is not a straight forward processes, rather it is a complex process that requires a lot of investment in terms of time, energy and money. Interviewee SZ commented that:

"*My product is actually a market ready product. Industry can buy and add this vitamins to their main product such as bread, rice etc to make it a healthier food"*. Similarly, interviewee DR highlighted that:

"The acceptance from the industry depends on the nature of the product. The product which is straight forward and ready to be used is more tendency to be accepted by industry. It is just matter of marketing. Like my product, for the brick it is also quite straight forward because you know it is used for construction". Thus market ready product is more preferable and interested by the industry to successfully collaborate with the academics.

Academic Researchers

Academic researcher needs to have a strong networking with industry partner to ensure that collaboration is a success one. Strong networking enable academic researcher to introduce his product to the outside world and enable him to understand business related issues. This networking benefits both parties; academic researchers to understand business related matters and industry partner to understand technical aspects of the product. There are many ways in which academic researcher will be able to have a strong networking with industry partner, as shared by interviewee RZ that:

"I have been active in nurturing technology. I started by my active involvement in non-profit organisation. It related to concrete. Now I am as a council member of Construction Society of Malaysia (CSM). Because of my active involvement in the society for more than 20 years, I also actively involved organising seminar and short courses. I also organised seminar on research and development in many places. So I get to know many people from there because of the fact that I shared my knowledge".

Building up a strong networking is one of the effective ways to introduce research products to the market place and to ensure that a collaboration is a success between these two parties. As shared by interviewee RZ above, he has the opportunity to learn more about his research product by communicating and building a networking with the industry partner. Furthermore, in producing and towards a better commercialisation, research products should tap the demand from the market. The experiences of being together with the industry has given good opportunity to the academic researcher in appreciating industry people in comparing the academic world.

It is said that lack of common knowledge and understanding between academic researcher and industry partner are considered as a challenge to link between them. Thus, academic researcher needs to identify and select their own industry partner because it is one of the key success for effective collaboration. This ability to set for finding suitable and right business partner may be gained through experiences. The right business partner able to understand academic and appreciate the research products. However, identifying and finding the right business partner is not an easy task, as interviewee DR commented,

"We went through hard time. We learnt through mistake. So now I'm ok. Because I become more matured. I know from the beginning when I start talking to people, I already know how their mentality and how they think. If I feel this guy is not good, then I just back off because for me he just look for funding only." Careful consideration need to be exercised in dealing with industry partner. Some of them may take advantage on the academics without giving full commitment in producing and commercialising research products. This was admitted by interviewee DR where he had a personal experience in dealing with this type of industry partner. So, it turned out to be unsuccessful collaboration between him and industry partner.

Strong determination and passion is another character of academic researcher whom industry partner are looking for. These characteristics are important to convince the industry partner to work with them effectively. Furthermore, these are character to ensure their products will enter the market successfully. When asking how they think about commercialisation, interviewee SZ claimed that:

"I think it is about passion. I love business since I was in school. It taught me a lots of things. It bring me out from laboratory and talk with many people"

On a different note, interviewee DR considered commercialisation as a way of learning new things. This is because traditionally university environment is used to teaching and learning per se, and commercialisation has just entered recently in the university setting. Commercialisation has changed the traditional setting of an academics in spending in the laboratory, but bringing their product into the market place. Passionate of doing commercialisation enable them to link with the industry. Equally agreed by interviewee EN that passionate of doing research and commercialisation activities is one of the best character encourage him to pursue for commercialisation. Furthermore, his main motivation towards commercialisation is for the benefit of the society and nation, not mainly for the monetary form. He said that:

"That is my aim, my passion [...] not only about money. It is the way on how I be able to contribute to my country". This statement was also agreed by interviewee AN that he wanted to be a pioneer (market leader) in his product, and he wanted to contribute back to the society. For this he said that:

"I want to be pioneer in this product. Because nobody has done this before and nobody has sold this before. So I want to be the first one. I want to challenge myself and at the same time I want to contribute to the country and society".

For commercialisation activities, academic researchers need to sacrifice their time, money and energy. Since commercialisation is a complex process, it requires a lot of time spent to successfully commercialise research product. Time is of the essence for the industry and they will consider if academic researcher is willing to sacrifice their time in pursuing the commercialisation activities. This was proved by interviewee AN where he stated that:

"I spent a lot of time in learning the process of commercialisation from the expert in other university. I focused on my teaching and research on the day and commercialisation in the evening. Sometimes until late at night just to learn about this".

Time sacrifices has convinced the industry partner to link with academic researcher, in order to ensure for the success of commercialisation process.

Academic researchers need to be creative to find their own income and generate income in pursuing for commercialisation, especially relevant during the tight budget. This experiences were shared by two of the interviewees, for them to attract industry partner to collaborate with them. Interviewee SZ observed that:

"I spent a lot of money at the beginning of the process of commercialisation. For example, the raw materials, I used my own money first. And when the demand is getting increase, I need to outsource in order to increase my production. I do contract of manufacturing. It cost my money as well. I used my money first before the pilot scale is ready. Sometimes it is not that quick to get the money from the university, so I need to invest first. I have spent around RM20 thousand for this. Now it has been 8 months". Similarly, interviewee LY stated that:

"I have spent a lot of money that some people don't know. I think, I have built a total about 6 buildings. The first one is outside the university. In Sri Gading. I have to rent a piece of land. Every month I pay RM500 to use the land and to build the first model house. So it lasted for more than 10 years. And actually I'm losing money you know".

Sufficient funding convinces the industry partner to effectively collaborate with academic researcher. Interviewee AN pointed his view:

"In order to get funded by university, we need to come out with our money first in order to convince the university on the practicality of our product. University also likes to see how determined we are in commercialisation". This was supported by interviewee DR who said that using his own money is one of the strategy to guarantee the success of collaboration. Thus, too much reliance on the university support in term of funding may not be justified to effectively collaborate with the industry partner. He said that:

"Don't expect university produce until really to the end user. But instead you have to interject once if you see the idea is good. You have to invest. You have to give your idea. You have to further educate those researcher, but you have to invest money on that."

Apart from the time and money that they have to sacrifice, academic researchers also need to dedicate their unlimited efforts for commercialisation to attract the industry partner to work with them effectively. Two academic researchers agreed that they have proved to give unlimited efforts to ensure that they reach the commercialisation stage effectively. Among the effort that academic researchers need to do is by doing their own marketing for their products. For this, interviewee SZ commented that:

"I do it on my own first. I sell it in a retail shop. Other than through university, I commercialise this on my own. I bring my product to whenever I go. I need to do this to increase the sales". On a similar vein, interviewee EN stated that:

"I do direct sales. When there is a conference or exhibition, I will promote and tell the people there about my product".

Clear vision, goal and objectives for commercialisation are also criteria to ensure the success of collaboration between academic researcher and industry partner. Interview AN was of the view that:

"I believe with this product. The market is large and it can give high impact to blind people. The market for this product might be niche but there is no competitor. We can monopoly the market. We can be the pioneer. Not number one, but only ONE…"

Since his product was of a kind in helping the blind people and eventually has become the market leader, interviewee AN proudly shared that he has reached the target, and this has set him for a clear vision, goal and gain the competitive advantage in the market.

Creative and innovative academic researchers are expected from the industry partner. Creative and innovative person can provide a solution especially in the critical time. Interviewee DR claimed that he encountered difficulty in finding suitable and adequate resources for his product. However, his creativity and innovative idea was to replace the old resource with a new one which enable him to produce a quality research products. Surprisingly, the new product that he produced is much better than the old product used with the existing inadequate resource. He (interviewee DR) emphasised that:

"I was stucked with the waste. I don't have waste for the brick. So I quickly looked for a solution. So I found another waste from another industry. So using that waste we produced, we started the formulation. Of course we have modified the formulation and we manage to produce brick and in fact the brick also a very good brick". Creativity and innovative engagement of academic researchers enable them to produce quality and surprise results from their research.

On the other circumstance, interviewee EN shared his experience,

"Actually before this, I sold thumb drive. We used flash technology in the thumb drive. It can only be install in one computer only. That can be said as the first one, the pioneer because nobody has done it before. However, we found it is not practical when the demand is increasing, we are not able to produce so many thumb drive in a short time. So we moved to internet, we developed the software on the internet. So people can buy through online as many as they prefer. It is much easy because we generate the system only".

Conclusions and Recommendations

This paper concludes that there are three main determinant factors to facilitate for an effective collaboration between academic and industry towards research product commercialization in Malaysia. Commercialization involves a very complex process which requires a flexible approach rather than one-size-fits all approach. Thus academic researchers should expect that along the process of commercialization there are many challenges that they need to face. Although there are many factors to determine the successful collaboration between academic researchers and industry partner, however this study only focuses on three main factors, namely role and function of the university, producing an innovative of research product and competency of the academic researcher. The role and function of the university in facilitating, encouraging, monitoring and sustaining the collaboration must be emphasized to become a commercialized university. The research product also must be creative and innovative to meet the market demand. Apart from this, the research product also must be based on the industrial needs to ensure for an effective collaboration. To emphasis for a better understanding, academic researcher should equip themselves with various skills to convince the industry partner to collaborate with them.

This study recommends that for an effective and strategic collaboration between academic researcher and industry partner, university should not only facilitate and link with the industry partner, but the most important function is to build, develop and sustain a good rapport. University also must practice careful consideration to develop and maintain a good rapport in selecting the most potential and appropriate industry partner. A well-defined function and role of these unit (research management centre or technology transfer office) must be set up in the university purposely helping academic researchers to collaborate with industry partner and to strengthen the position of product commercialization in the university. These centres are providing their assistance from the beginning until products reach the commercialisation level. Furthermore, appointed personnel must be competent in giving assistance in terms of business and management related skills as well as other rules and procedures for collaboration and commercialization. A clear responsibilities and rights are needed to ensure that each parties appreciate and understand each other's rights and function. Building a good rapport and examine what are the demands of the industry are important for a successful collaboration of the research product commercialization. Regarding the research product, in order to attract industry partner academic researcher should produce a unique and innovative products. Merely producing a research product without carry any value for commercialization will be treated less significant by the industry partner. Thus, research product must have commercial value and solve the existing problems in the market. Moreover, the product produced must have a competitive advantages in comparing with other available research products. Academic researchers should equip themselves with various knowledge, for example intellectual property and commercialisation and other business and management related skills. Furthermore, they need to enhance with other skills including negotiation, leadership and communication skills to have a common knowledge and understanding with industry partner. Industry partner also must be encouraged to have basic technical knowledge in areas related to academic researcher for them to appreciate the academic role. The effort of bridging two worlds, academic and industry must be made possible. Thus, understanding and adaptability are needed to avoid any mismatch between academic researcher and industry partner. Furthermore the link between them must be made in a concerted efforts to achieve a common goals for commercializing research products.

Acknowledgement

We would like to express our sincere gratitude to the Universiti Teknikal Malaysia Melaka for supporting this research under a grant of FRGS/1/2014/SS05/FPTT/02/F00226.

Abstract

This article analyzes the relationship between social capital, entrepreneurship and economic growth for a panel of developed and developing countries during the period 1990-2004. Our study will be conducted using static and dynamic panel data method and a simultaneous equations model. The main results of this study are, first, the level of social capital and growth are significantly and positively correlated, on the other hand, social capital can also have indirect effects on economic growth through other variables specifically through entrepreneurial activity.

Keywords: Social capital, entrepreneurship, economic growth, panel data.

Résumé

Cet article analyse la relation entre le capital social, l'entrepreneuriat et la croissance économique d'un panel de pays développés et en développement au cours de la période 1990-2004. Notre étude sera effectuée en utilisant la méthode des données de panel statique et dynamique, ainsi qu'un modèle à équations simultanées. Les principaux résultats sont, d'abord, le niveau du capital social et de la croissance sont positivement et significativement corrélés, d'autre part, le capital social peut également avoir des effets indirects sur la croissance économique par le biais d'autres variables et plus précisément par le biais de l'activité entrepreneuriale.

Mots clés: Capital social, entrepreneuriat, croissance économique, données de panel.

Introduction

La croissance économique désigne le processus par lequel la production réelle nationale de biens et de services augmente régulièrement au cours du temps. Depuis Smith (1776) la question de la croissance des économies constitue l'une des préoccupations centrales de la recherche économique. Durant son développement, la théorie de la croissance s'est concentrée sur des variables telles que le travail, le capital et le progrès technique, et à la façon dont les facteurs sont combinées entre eux pour expliquer les différences de croissances entre pays. Pour expliquer ces différences de croissance, les études économiques ont abordé des déterminants profonds tels que la qualité des institutions, le capital social et l'entrepreneuriat afin de compléter le schéma théorique de la croissance.

En effet, l'intérêt pour l'étude de l'entrepreneuriat réapparu avec plus d'intensité dans les années 70, avec un accent sur les théories économiques par le biais des constations empiriques et réflexions théoriques. Il a été constaté que plusieurs pays développés, principalement en Europe, ont lancé de nouvelles initiatives, après des années de ralentissement économique et de déclin de la création d'entreprise. D'autres parts, des réflexions théoriques qui ont marqué l'économie mondiale, se reflètent dans les économies nationales. Ces changements indiquent que la croissance économique a été soutenue non seulement dans les économies d'échelle ou de gamme, mais que les entreprises ont un rôle important dans la croissance économique.

Ainsi, un des facteurs importants dans la réussite ou non d'un processus de création d'une nouvelle entreprise et qui aide l'entrepreneur à contrer ces difficultés est sa capacité à développer et à mobiliser son capital social. Le capital social désigne les réseaux de relations d'un acteur individuel

ou collectif et les ressources qu'il peut mobiliser grâce à ces réseaux, il permet à l'entrepreneur d'obtenir des ressources qui, autrement, ne lui seraient pas accessibles, mais d'une façon plus onéreuse en termes de temps, de coûts ou d'efforts pour les acquérir. En ce sens, deux avantages directs sont obtenus à partir du capital social pour les entrepreneurs: les ressources et les informations. L'existence d'un groupe de personnes qui doivent être intéressés à prendre des risques sur leurs fonds afin de générer de nouvelles entreprises engendre un effet positif de l'activité entrepreneuriale sur la croissance économique.

Les études sur le capital social menées jusqu'ici dans le champ de l'entrepreneuriat ont bien montré son importance pour les projets de création d'entreprises. En général, la littérature a considéré que l'importance du capital social dans le domaine de l'entrepreneuriat a été attribué au fait qu'ils fournissent des ressources, l'accès à des ressources ou du soutien affectif. En ce sens, la pertinence est due au fait que l'entrepreneuriat est liée à l'innovation et à l'avantage concurrentiel. Par conséquent, une relation positive entre le capital social et l'entrepreneuriat est prévu et d'une manière indirecte, il permettrait également de renforcer la croissance économique.

Généralement, nous constatons dans l'analyse empirique une corrélation positive et significative de l'effet du capital social sur le taux de croissance du PIB par habitant, mais sans insister sur les différents canaux de transmission. En d'autres termes, outre l'effet direct que le capital social peut exercer sur la croissance économique, la structure sociale peut également avoir des effets indirects sur l'activité réelle par le biais d'autres variables qui, à leurs tours, affectent la croissance. Dans la littérature à ce sujet, le capital social mesuré par le niveau de confiance dans l'économie est un facteur déterminant de l'activité d'investissement, du capital humain, de la qualité des institutions, du développement financier et de l'activité entrepreneuriale.

1. Définition et importance du capital social

Le concept de capital social n'est pas nouveau et remonte au moins à Hanifan (1916) qui a souligné l'importance de la participation communautaire dans l'amélioration de la performance scolaire. L'auteur définit le capital social comme *« ces substances tangibles qui comptent le plus dans la vie quotidienne des gens à savoir, la bonne volonté, la camaraderie, la sympathie et les relations sociales entre individus et familles ».* Plus tard, Banfield (1958) a utilisé le concept de capital social pour tenir compte du déclin économique du sud de l'Italie. D'autres travaux ont fait usage de ce terme, parfois avec des variations dans la signification (Homans (1961), Jacobs (1971) et Loury (1977)) pour suggérer que la mobilisation des relations sociales et la coopération peuvent aider les individus à améliorer leur bien-être.

Mais, la popularisation de ce concept, pendant les dernières décennies, est due à Bourdieu (1980, 1986) qui s'est aussi servi de la notion de capital social pour faire référence à certains types de ressources qui découlent de l'appartenance à des associations, communautés et réseaux sociaux. Bourdieu a été le premier à donner une définition précise du capital social : *« Le capital social est l'ensemble des ressources actuelles ou potentielles qui sont liées à la possession d'un réseau durable de relation plus ou moins institutionnalisées, ou en d'autres terme, à l'appartenance à un groupe ».* Coleman (1988, 1990) a donné une nouvelle dimension à ce concept en le définissant par sa fonction, où il est reconnu comme une variété d'entités avec deux éléments communs : des caractéristiques de structures sociales et la facilitation des actions individuelles au sein de la structure. Pour Coleman (1988) : *« Le capital social désigne la capacité des individus à travailler ensemble pour un objectif commun dans des groupes ou organisations ».* Dans le début des années 90, ce concept sociologique a connu une renaissance puisqu'il a été adopté par des politologues comme Putnam (1994) et Fukuyama (1995). Putnam définit le capital social comme «*les caractéristiques de la vie sociale telles que les réseaux, les normes et la confiance mutuelle, qui permettent aux participants d'agir ensemble plus efficacement pour atteindre des objectifs partagés»*. (Putnam, 1995, p. 67). On peut dire alors que le capital social a été défini de différentes façons par les différents chercheurs et l'on peut considérer comme un ensemble de réseaux, de normes et de valeurs qui facilitent la coopération

intra-groupe et inter-groupe pour l'obtention des bénéfices mutuels. Étant donné que le capital social a un aspect de qualité, alors, il est difficile à mesurer. En fait la mesure du capital social se rapporte à des sujets tels que la fiabilité ; la participation volontaire à des associations et instituts de charité ; l'appartenance à des organisations et des clubs... Plusieurs chercheurs ont essayé de trouver des indicateurs du capital social : Coleman (1988), dans son étude sur la contribution du capital social au capital humain, Putnam (1993 / 2000) dans ses études sur les relations entre capital social et performance économique, Knack et Keefer (1997) relativement aux liens entre capital social et résultats économiques. Ces auteurs utilisent généralement trois types d'indicateurs pour mesurer le capital social : l'adhésion aux associations locales et aux réseaux, les indicateurs de confiance et adhérence aux normes et les indicateurs d'action collective.

2. Définition et importance de l'entrepreneuriat

Bien que l'intérêt de l'entrepreneuriat n'est pas nouveau, le terme entrepreneur a été utilisé pour la première fois dans un contexte économique en 1755 et attribuée à Richard Cantillon. Dès lors, de nombreux livres et articles ont été écrits sur des sujets liés à l'entrepreneuriat. En conséquence de l'attention croissante du sujet, l'entrepreneuriat a été étudié en utilisant des approches différentes : psychologique, sociologique, anthropologique, et bien sûre économique. Cela reflète la complexité de la définition de l'entrepreneuriat, ainsi le concept est clairement ouvert à la recherche fondée sur des motifs divers. Nous utilisons comme point de départ les contributions et les idées de trois économistes: Joseph A. Schumpeter (1934), William J. Baumol (1968) et Israel M. Kirzner (1973).

Pour Schumpeter l'entrepreneuriat se produit quand il ya de l'innovation dans l'introduction d'un nouveau produit ou d'une nouvelle organisation. Par conséquent, sa compréhension d'un entrepreneur était une abstraction conceptuelle caractérisée par la création de nouvelles combinaisons. Plus précisément :

« Quel qu'il soit, l'individu en question sera entrepreneur ou non selon qu'il réalisera ou non des combinaisons nouvelles. Il perd donc ce caractère s'il continue à exploiter l'entreprise considérée selon un circuit » (Schumpeter, 1934).

« *Et qu'ont-ils fait : ils n'ont accumulé aucune sortes de marchandises, ils n'ont pas créé des moyen de production original, mais ils ont employé des moyens de production existants de manière différentes, de façon plus appropriées et plus avantageuses. Ils ont effectué de nouvelles combinaisons. Ils sont des entrepreneurs. Et leur profit, le surplus que ne contrebalance aucun passif, est un profit d'entrepreneur* » (Schumpeter, 1934).

Ainsi, lorsqu'un entrepreneur cesse d'innover, il cesse d'être un entrepreneur. En outre, pour Schumpeter, l'entrepreneuriat et l'innovation de l'entrepreneur conduisent à une « *destruction créatrice* » dans les marchés et les secteurs de l'économie parce que des nouveaux produits et des business modèles arrivent et remplacent les anciens. Ainsi, la « *destruction créatrice* » est à l'origine de la croissance économique à long terme.

Reprenant les travaux de Joseph Schumpeter sur l'innovation, William Baumol insiste sur le rôle de l'innovation dans la concurrence entre les firmes. L'entrepreneur est un innovateur, qui est toujours engagé à faire quelque chose qui n'a jamais été faite avant. Baumol montre que si le nombre total d'entrepreneurs (l'intensité entrepreneuriale) varie selon les sociétés, leur contribution à la croissance varie encore plus selon leur allocation plus ou moins productive selon les périodes et les cultures étudiées (1990). Pour lui, le fond du problème, c'est que la répartition des entrepreneurs entre bons ou mauvais dépend de leurs rendements relatifs. Par conséquent, les incitations adéquates et les institutions solides qui soulèvent la récompense par rapport à l'entrepreneuriat productif devraient être conçues.

Selon Baumol l'entrepreneuriat productif est favorisé « *par les incitations pour les entrepreneurs de se consacrer à l'innovation productive plutôt que la recherche de rente novatrice ou même à des occupations destructrices, telles que des activités criminelles* ». (Baumol, 2002)

Ainsi, Baumol distingue entre les entrepreneurs et met l'accent sur la pertinence intrinsèque du contexte économique dans la détermination de l'entrepreneuriat productive. Enfin, pour Baumol l'entrepreneur est un innovateur. Plus précisément « *Il cherche en permanence la possibilité d'introduire de nouveaux produits et de nouvelles procédures, d'envahir de nouveaux marchés, et de créer de nouvelles formes d'organisation* ». (Baumol, 2002)

Kirzner met en valeur le rôle crucial de l'entrepreneur dans l'équilibrage des marchés. Pour lui le profit entrepreneurial est un pur profit qui n'est pas lié à l'utilisation des facteurs de production. Il provient d'une décision simultanée d'achat et de vente suite à la découverte de différences de prix avantageuses, dont l'existence est basée sur l'ignorance des agents sur la demande et l'offre précises. Jusqu'ici les agents économiques ignorent les opportunités de profit, qui ne peuvent être découvertes que par la seule mise en place d'investissements spécifiques, elles dépendent avant tout des capacités des individus et en particulier de leur « *vigilance* ».

Kirzner affirme donc que les opportunités existent à cause de l'ignorance des acteurs du marché et les entrepreneurs sont les rares individus qui tireront un avantage de ces insuffisances du marché. Ainsi les opportunités existent tout autour de nous dans l'espace et dans le temps, mais c'est seulement les individus dotés de ce que Kirzner appelle « *vigilance* » qui possèdent la capacité de les identifier. La perception des opportunités de profit dépend donc de la vigilance de l'entrepreneur aux différentiels dans la dotation en information des individus sur le marché.

3. Capital social, entrepreneuriat et croissance économique

Comme il est déjà mentionné, le capital social a un impact sur le développement et la croissance par le biais de divers mécanismes. Par exemple, Knowles (2005) identifie quatre groupes principaux, qui couvrent les différentes façons dont le capital social contribue à la croissance économique. Le premier se réfère à « *l'augmentation du nombre de transactions mutuellement bénéfiques* » illustré par divers exemples de coopérations fondées sur la confiance et l'information. Le deuxième grand groupe se réfère à « *la résolution des problèmes d'action collective* » qui stipule que les entreprises ayant un degré élevé de capital social résolues les problèmes d'action collective plus facilement que ceux ayant un faible niveau de capital social. « *La réduction des coûts de surveillance et de transaction* » est un autre mécanisme pour que le capital social fonctionne, principalement par la confiance. Enfin, le capital social contribue à « *l'amélioration de la circulation de l'information* » à travers des groupes sociaux ou des réseaux.

Aussi Greve et al. (2006) soulignent que : le capital social a quatre effets principaux : l'obtention d'informations; le transfert de connaissances, l'innovation et la diffusion des technologies ou des pratiques; la combinaison des connaissances complémentaires et d'aide à la résolution des problèmes; et le courtage. Ils montrent d'autres aspects dans lesquels le capital social contribue à augmenter la productivité et contribue à stimuler l'entrepreneuriat : l'un est l'utilisation des relations sociales pour mobiliser les gens à contribuer à un projet, l'autre est l'utilisation du capital social des membres de l'équipe pour augmenter et compléter les connaissances de l'équipe. L'utilisation du capital social des membres de ces réseaux sociaux, des ressources de l'entreprise ou de l'équipe peuvent être renforcées et complétées, car une communauté d'individus rassemble toujours plus de ressources qu'une seule personne. Greve et al montrent donc la valeur du capital social comme capital productif qui ne dépend pas seulement du nombre de contacts dans ces relations sociales, mais qui influence également sur les contacts indirects qui seront reflétées dans la structure du réseau.

Spellerberg, 2001, a déclaré que « l'accès au capital social peut être considéré comme ayant trois fonctions principales: *le traitement de l'information, l'évaluation des risques et des opportunités* et

l'évaluation des situations, des personnes et des organismes». Ces trois fonctions sont importantes dans la société, parce que l'information est un élément clé de l'entrepreneuriat et de la croissance.

Ainsi, comme nous pouvons le voir, le capital social et l'entrepreneuriat jouent un rôle clé dans le développement. Le capital social est un facteur important dans la diffusion des connaissances dans la société en général et les entreprises en particulier, en facilitant les flux d'informations et le transfert de l'innovation et l'entrepreneuriat affecte le développement économique en augmentant le niveau des revenus ou en réduisant le niveau de chômage. Koo & Kim, 2009, affirment que les politiques de recherche et développement doivent être discutées dans le contexte plus large de questions régionales relatives, telles que l'entrepreneuriat, la recherche universitaire, le capital humain, le capital social et les structures de l'industrie. Ce sont des questions interdépendantes qui doivent être examinées dans un cadre politique plus globale. Ils ont proposé un modèle de croissance économique dans lequel le taux de croissance économique régionale est une fonction du taux de croissance de la connaissance locale économiquement utile, combinée avec les taux de croissance du capital et du travail. La croissance de la connaissance locale économiquement utile est une fonction de la R&D, de l'entrepreneuriat, de la recherche universitaire, du capital humain, du capital social et de la structure de l'industrie. Leurs résultats indiquent que l'entrepreneuriat joue un rôle important dans la croissance régionale. De plus, pour un niveau donné des dépenses, l'industrie R&D et le niveau de l'activité entrepreneuriale détermine combien d'avantage un Etat peut recueillir de son activité de recherche.

Vázquez-Rozas et al. (2010) afin de tester l'effet de l'entrepreneuriat sur la croissance économique utilisent le ratio d'entreprises créées dans chaque région par rapport au nombre total d'entreprises pendant neuf ans (2000 à 2008) comme approximation du capital entrepreneurial. Ils estiment un modèle économétrique sur données de panel, et ils trouvent un effet positif de la variable entrepreneuriat sur la croissance du PIB par habitant. En outre, ils constatent que le capital humain et le capital social sont significatifs.

4. Analyse empirique de la relation entre le capital social, l'entrepreneuriat et la croissance économique

Notre objectif dans cette partie est d'étudier empiriquement le lien entre le capital social, l'entrepreneuriat et la croissance économique pour un échantillon de 40 pays développés et en développement en utilisant des données sur la période 1990-2004. Pour cela nous utilisons la méthode des données de panel statique et dynamique. En conséquence, nous réalisons tout d'abord des estimations sur un modèle à effets individuels. Ensuite, nos estimations porteront sur le modèle dynamique où nous introduisons la variable endogène retardée comme variable explicative pour voir si la croissance économique d'une année est influencée par celles des années passées.

4.1. Spécification du modèle économétrique

A la suite des travaux de Gregory N. Mankiw, David Romer, et David Weil (1992), Demetriades et Law (2004), l'objectif de notre étude empirique, est d'ajouter d'autres déterminants de la croissance économique dans l'équation du modèle de croissance de Solow, traitant de la relation entre le capital social, l'entrepreneuriat et la croissance économique. Par conséquent, nous tenons compte du modèle suivant comme équation à estimer:

$$Y_{it} = \alpha_i + \beta 1\ lgdp\_f_{it} + \beta_2\ lKS_{it} + \beta_3\ lKH_{it} + \beta_4\ lINV_{it} + \beta_5\ lDF_{it} + \beta_6\ lQI_{it} + \beta_7\ lE_{it} + \varepsilon_i \qquad [1]$$

Où i et t dénotent respectivement le pays et le temps.

Pour i = 1,……, 40/ t = 1990,……, 2004.

Avec αi l'effet spécifique individuel, β1, β2, β3, β4, β5, β6 et β7 sont les paramètres à estimer dans ce modèle et εit est le terme d'erreur.

4.2. Présentation des variables et de leurs sources

Les variables qui seront présentées sont recueillies pour un panel de 40 pays développés et en développement au cours de la période 1990-2004. La variable dépendante est le taux de croissance du PIB réel par tête (Y_{it}) et les variables indépendantes sont le logarithme du PIB initial (lgdp_f) qui sert à contrôler la convergence, le capital humain (KH), le taux d'investissement par rapport au PIB (INV), le développement financier (DF), la qualité de l'environnement institutionnel (QI), le capital social (KS) et l'entrepreneuriat (E).

Le capital humain est mesuré par la moyenne des années d'éducation secondaire, le capital physique est mesuré par la formation brute du capital fixe, le développement financier est mesuré par le ratio du passif quasi-liquide, la qualité des institution est mesuré par l'indice de liberté civile publié par Freedom house compris entre 1 et 7 (1 pays à degré de liberté civile élevé, 7 pays à degré de liberté civile faible), le capital social est mesuré par l'indices de confiance et de densité associative, et enfin l'entrepreneuriat est mesuré par le nombre des brevets déposés par les résidents et les non-résidents.

4. 3. Méthode d'estimation et interprétation des résultats

La structure du modèle telle qu'elle a été présentée ci-dessus, nous conduit à réaliser des estimations sur un modèle de panel hétérogène. Ainsi, nous utilisons deux méthodes d'estimations. Dans une première étape, nos estimations portent sur la méthode des données de panel statique, elle permet de prendre en compte l'hétérogénéité inobservée des pays de l'échantillon. Les caractéristiques individuelles peuvent être de nature déterministe ou aléatoire. Le test de spécification de Hausman permet de choisir l'une ou l'autre de ces spécifications. Le modèle à effets fixes (MEF) sera retenu si la probabilité attachée à la statistique de test de Hausman est inférieur à 10%. Sinon, on retient le modèle à effet aléatoire (MEA). Dans une deuxième étape, les méthodes économétriques suivies sont la méthode des moments généralisés GMM (*General Method of Moment*) en panel dynamique ainsi qu'un modèle à équations simultanées pour résoudre la question d'endogénéité du capital social.

4. 3.1. La méthode des données de panel statique

Tests de spécification

En estimant un échantillon en données de panel, la première chose qu'il faut vérifier c'est la spécification homogène ou hétérogène des données, autrement dit de savoir si l'on a le droit de supposer que le modèle théorique étudié est parfaitement identique pour tous les pays, ou au contraire s'il existe des spécificités propres à chaque pays.

On commence à tester l'hypothèse d'une structure parfaitement homogène (constante et pente identiques). Si les statistiques de Fisher associées au test d'homogénéité totale sont supérieures au Fischer de la table statistique, on rejette donc cette hypothèse. Ensuite, on teste la présence des effets individuels en supposant ainsi que les β_i sont constantes pour tous les pays.

Pour ce type de modèle, on distingue deux cas : le cas où les paramètres α_i sont des constantes déterministes (modèle à effets fixes) et le cas où les paramètres α_i sont des réalisations d'une variable aléatoire d'espérance et de variance finie (modèle à effets aléatoires). Il faut donc savoir quel est le bon modèle pour notre échantillon. Nous procédons donc à une analyse de test de spécification de Hausman.

Tests de Hausman

Rappelons que le test de spécification de Hausman (1978) est un test de spécification des effets individuels. Il sert à discriminer les effets fixes et aléatoires. L'hypothèse testée concerne la corrélation entre les effets individuels et les variables explicatives :

$$\begin{cases} H0 : E(\alpha i \setminus Xi) = 0 \\ H1 : E(\alpha i \setminus Xi) \neq 0 \end{cases}$$

Sous H_0, le modèle peut être spécifié avec des effets individuels aléatoires et l'on doit alors retenir l'estimateur des MCG (estimateur BLUE). Sous l'hypothèse alternative H_1, le modèle doit être spécifié avec des effets individuels fixes et l'on doit alors retenir l'estimateur Within (estimateur non biaisé). La statistique de test de Hausman appliquée au test de spécification des effets individuels est la suivante :

$$H = (\hat{\beta}_{within} - \hat{\beta}_{MCG})' \, [Var\,(\hat{\beta}_{within} - \hat{\beta}_{MCG})]^{-1} \, (\hat{\beta}_{within} - \hat{\beta}_{MCG})$$

Sous H_0, la statistique H suit asymptotiquement un Chi-deux (χ^2) à K degrés de liberté.

Résultats d'estimation

En utilisant la méthode des données de panel statique pour 40 pays en développement sur la période 1990-2004, on obtient les résultats présentés dans le tableau suivant.

Tableau 1: effets directs du capital social sur la croissance économique (panel statique)

Variable dépendante : Croissance du PIB réel par tête (Y_{it})	MEF	
	(1)	(2)
lgdp_f	-0.0888 (0.0332)***	-0.1305 (0.0374)***
lKS	0.0008 (0.0004)*	0.0008 (0.0005)*
lKH	-	0.0247 (0.2002)
lINV	-	0.0105 (0.0302)
lDF	-	0.0075 (0.0197)
lQI	-	-0.0169 (0.0280)
lE	-	0.0125 (0.0056)**
Constante	0.8541 (0.3017)***	1.1106 (0.3225)***
Observations	200	200
R2	0.5930	0.6411
Test de Hausman	0 0057	0.0101

*Notes : ***significativité à 1%, ** significativité à 5%, * significativité à 10%. La période d'étude 1990-2004 est subdivisée en Cinque sous-périodes de trois années chacune. Toutes les variables sont exprimées en logarithme népérien. Le test de Hausman correspond à la statistique du test de Hausman, avec la p-value entre parenthèses.*

D'après les résultats d'estimation, nous constatons que la statistique de Fisher calculée est supérieure à celle de la table statistique. Ceci nous amène à conclure qu'on doit rejeter l'hypothèse nulle celle

d'homogénéité interindividuelle. Autrement dit, il faut privilégier un modèle tenant compte des spécificités individuelles.

Pour la régression (1), la réalisation de la statistique du test de Hausman est de 10,35. Etant donné que le modèle comporte deux variables explicatives (K = 2), cette statistique suit un Khi deux à deux degrés de liberté. Le seuil est de 5,992. Nous rejetons donc l'hypothèse nulle d'absence de corrélation entre les effets individuels et les variables explicatives. Ainsi, nous devons privilégier l'adoption d'un modèle à effets fixes et retenir l'estimateur Within. La régression (1) montre que le capital social présente un coefficient positif et significatif. En plus, le PIB initial présente également un coefficient négatif et significatif qui confirme l'hypothèse de convergence conditionnelle, comme dans Mankiw, Romer et Weil (1992), où les pays en développement ont tendance à croître plus rapidement que les pays développés.

Dans la régression (2), nous introduisons les autres déterminants de la croissance économique à savoir le capital humain (KH), le taux d'investissement (INV), le développement financier (DF), l'entrepreneuriat (E) et la qualité des institutions (QI) qui est mesuré par l'indice de liberté civile compris entre 1 (pays à degré de liberté civile élevé) et 7 (pays à faible degré de liberté civile), par conséquent nous espérons un coefficient négatif lorsque nous utilisons l'indice de liberté civile. La réalisation de la statistique du test de Hausman est de (18,46). Le modèle (2) comporte sept variables explicatives (K = 7), cette statistique suit un Khi deux à sept degrés de liberté. Le seuil est de 14,067. On constate que les estimations retenues, seront celles des modèles à effets individuelles fixes. Le capital social a conservé son importance statistique significative par rapport à la régression précédente. L'entrepreneuriat mesuré par le nombre des brevets déposés par les résidents et les non-résidents a un impact positif et significatif sur la croissance économique. Ce constat est conforme à la littérature théorique et empirique présentées ci-dessus.

Après avoir effectué nos estimations en utilisant les effets fixes, nous allons procéder dans une deuxième étape aux estimateurs GMM d'Arellano-Bond. Chacune de ces techniques à ses propres mérites. L'analyse de régression à effets fixes tient compte des effets fixes par pays et produit des estimateurs convergents des coefficients, à condition qu'il n'y ait pas de problème d'endogénéité et la variable dépendante retardée n'est pas inclus dans l'analyse. L'analyse GMM tient compte des effets fixes par pays et produit des estimateurs convergents en présence de la variable dépendante retardée. En outre, en incluant la variable dépendante retardée dans l'analyse, dans une certaine mesure, la méthode GMM tient compte du problème d'endogénéité. Ce qui explique l'utilisation exponentielle des données de panel dynamique dans les travaux récents sur la croissance.

4. 3.2. La méthode des données de panel dynamique

Un modèle dynamique est un modèle dans lequel un ou plusieurs retards de la variable dépendante figurent comme variables explicatives. Cette méthode permet de résoudre les problèmes de biais de simultanéité, de causalité inversée et de variables omises qui affaiblissent les résultats antérieures. Elle permet aussi de traiter le problème de l'endogénéité de toutes les variables explicatives. Il existe deux variantes d'estimateur des GMM en panel dynamique : l'estimateur GMM en première différence et l'estimateur GMM en système. L'estimateur GMM en système combine dans un seul système une régression en différence et une régression en niveau (Arellano et Bover, 1995 ; Blundell et Bond, 1998). Dès lors, l'estimateur GMM en système est le mieux approprié pour notre essai empirique. Deux tests sont associés à l'estimateur GMM en panel dynamique : le test de suridentification de Sargan/Hansen, qui permet de tester la validité des variables retardées comme instruments, et le test d'autocorrélation d'Arellano et Bond où l'hypothèse nulle est l'absence d'autocorrélation de premier ordre des erreurs de l'équation en niveau. Dans nos régressions, les résultats de ces deux tests sont conformes à nos attentes. En effet, les statistiques ne permettent pas de rejeter l'hypothèse Ho, celle de la validité des variables retardées comme instruments.

Résultats d'estimation

En partant de l'équation [1], les estimations ont été réalisées avec la méthode du GMM *system* en panel dynamique : en introduisant la variable endogène retardée comme variable explicative. On obtient ainsi l'équation [2]:

$$Y_{it} = \alpha_i + \beta_1 Y_{it\_1} + \beta_2 \, lgdp\_f_{it} + \beta_3 \, lKS_{it} + \beta_4 \, lKH_{it} + \beta_5 \, lINV_{it} + \beta_6 \, lDF_{it} + \beta_7 \, lQI_{it} + \beta_8 \, lE_{it} + \varepsilon_{it} \qquad [2]$$

Les résultats d'estimation sont présentés dans le tableau (2).

Tableau 2: effets directs du capital social sur la croissance économique (panel dynamique)

Variable dépendante : Croissance du PIB réel par tête (Y_{it})	GMM System	
	(1)	(2)
Y_{it_1}	-0.0980 (0.1404)	-0.0497 (0.1451)
lgdp_f	0.0764 (0.0473)	0.0246 (0.0342)
lKS	0.0011 (0.0007)*	0.0014 (0.0008)*
lKH	-	0.0549 (0.0248)**
lINV	-	0.0325 (0.0382)
lDF	-	-0.0250 (0.0354)
lQI	-	-0.0060 (0.0446)
lE	-	0.0022 (0.0092)
Constante	-0.6399 (0.4254)	-0.2295 (0.3035)
Observations	160	160
Test de Hansen	0.622	0.274
AR(2)	0.483	0.633

*Notes : ***significativité à 1%, ** significativité à 5%, * significativité à 10%. La période d'étude 1990-2004 est subdivisée en Cinque sous-périodes de trois années chacune. Toutes les variables sont exprimées en logarithme népérien. Le test de Hansen correspond à la statistique du test de validité des instruments pour l'estimation en GMM, avec la p-value entre parenthèses : l'hypothèse nulle est la validité des variables retardées en niveau et en différences comme instruments. AR(2) : statistique d'Arellano-Bond du test d'autocorrélation des erreurs de second ordre, avec la p-value entre parenthèses : l'hypothèse nulle est l'absence d'autocorrélation de second ordre.*

Pour l'estimateur GMM *system*, les statistiques de diagnostic sont favorables. Le test de suridentification de Hansen ne rejette pas la validité des instruments utilisés et le test d'Arellano et Bond ne rejette pas l'autocorrélation à l'ordre 2. Les résultats des différentes régressions effectuées avec la méthode du GMM *system* en panel dynamique confirme l'effet positif et significatif du capital social sur la croissance économique. Les résultats montrent aussi qu'il existe une relation positive et significative entre le capital social et le capital humain. Néanmoins, les autres variables sont étonnamment jugées non significatives, malgré le signe positif. Ces résultats peuvent s'expliquer par la présence du niveau initial de revenu comme une variable explicative.

Il en résulte donc que le capital social a deux effets sur la croissance économique : un premier effet direct vient du fait que le capital social peut être considéré comme un déterminant de la croissance économique comme le capital physique ou humain (Coleman (1988)). Un deuxième effet indirect est transmis à la croissance économique à travers les autres variables mentionnées : la qualité des institutions, l'éducation, l'investissement, le développement financier et l'entrepreneuriat.

Pour distinguer les effets directs et indirects du capital social sur la croissance économique, nous utilisons un modèle à équation simultanées.

4. 3.2. Modèle à équations simultanées

Effets indirects des canaux de transmission sur le capital social

Pour tester empiriquement l'effet du capital social sur chaque canal de transmission, nous avons effectué une série de régressions qui sont présentées dans l'équation [3], ensuite nous avons utilisé un modèle à équations simultanées (équation [4]), qui permet aussi de surmonter le problème d'endogénéité. Les résultats des estimations sont présentés dans le tableau ci-dessous :

$$\begin{cases} lKH_{it} = \alpha_i + \beta_1\, lgdp\_f_{it} + \beta_2\, lKS_{it} + \varepsilon_{it} \\ lINV_{it} = \alpha_i + \beta_1\, lgdp\_f_{it} + \beta_2\, lKS_{it} + \varepsilon_{it} \\ lDF_{it} = \alpha_i + \beta_1\, lgdp\_f_{it} + \beta_2\, lKS_{it} + \varepsilon_{it} \\ lQI_{it} = \alpha_i + \beta_1\, lgdp\_f_{it} + \beta_2\, lKS_{it} + \varepsilon_{it} \\ lE_{it} = \alpha_i + \beta_1\, lgdp\_f_{it} + \beta_2\, lKS_{it} + \varepsilon_{it} \end{cases}$$

L'estimation de ces équations permet de prendre en compte les effets indirects du capital social sur la croissance économique.

Tableau 3: effets indirects du capital social sur la croissance économique (estimation par la méthode des équations simultanées)

Variable dépendante	lKH	lINV	lDF	lQI	lE	Y_{it}
	[3]					[4]
lgdp_f	0.3348 (0.1854)*	0.3557 (0.1217)***	0.5492 (0.1892)***	0.1263 (0.1256)	0.9211 (0.6581)	-0.2992 (0.0367)***
lKS	0.0047 (0.0017)***	0.0040 (0.0011)***	-0.0003 (0.0017)	-0.0004 (0.0011)	0.0037 (0.0062)	0.0007 (0.0003)**
lKH						0.0085 (0.0152)
lINV						0.0451 (0.0230)**
lDF						0.0091 (0.0150)
lQI						0.0193 (0.0223)
lE						0.0103 (0.0042)**
Constante	-1.7655 (1.5664)	0.4208 (1.0280)	-1.8263 (1.5985)	0.5825 (1.0612)	-2.5769 (5.5591)	2.2577 (0.3040)***
Observations	200	200	200	200	200	200

*Notes : ***significativité à 1%, ** significativité à 5%, * significativité à 10%. La période d'étude 1990-2004 est subdivisée en Cinque sous-périodes de trois années chacune*

L'estimation des équations rapportées dans l'équation [4], montre que l'investissement et l'entrepreneuriat sont positifs et significatifs. Le Tableau (3) révèle également que le capital social est positivement et significativement corrélé avec la croissance économique. En d'autres termes, après avoir pris en compte les effets indirects du capital social sur la croissance économique à travers les canaux de transmissions, nous constatons que le capital social devient significatif au seuil de confiance de 5%. En plus, l'entrepreneuriat mesuré par le nombre des brevets déposés par les

résidents et les non-résidents a un impact positif et significatif sur la croissance économique. L'entrepreneuriat devient aussi significatif au seuil de confiance de 5%.

Dans d'autres études sur le lien entre la confiance et la croissance, Knack et Keefer (1997) ont trouvé qu'une augmentation d'un écart-type dans le niveau actuel de confiance est associée à une augmentation de la croissance économique de plus de la moitié d'un écart-type. Selon Zak et Knack (2000) la croissance économique augmente d'environ 1% en moyenne suite à une augmentation de 15 % de la confiance. Un tel résultat s'est avéré robuste dans les travaux de Beugelsdijk, De Groot et van Schaik, (2004) qui ont utilisés l'analyse extrêmes liés.

Néanmoins, à notre connaissance, toutes ces contributions n'ont pas explicitement étudié les canaux de transmission de capital social à la croissance économique. C'est pourquoi le but de ce travail est de centrer l'analyse sur ces aspects en étudiant la contribution relative de chacun des déterminants de la performance économique.

Conclusion

L'objet de ce travail est d'étudier empiriquement les effets directs et indirects du capital social sur le taux de croissance du PIB par tête pour un échantillon de pays développés et en développement. Pour cela, nous utilisons l'économétrie des données de panel en résolvant les problèmes d'endogénéité de la variable indépendante, en l'occurrence, le capital social.

Dans ce contexte, nous avons présenté une synthèse des relations entre le capital social, l'entrepreneuriat et la croissance économique. La perspective du capital social suppose que les liens des réseaux sociaux fournissent des individus ou des organisations ayant accès au savoir et à d'autres ressources utiles. Les réseaux sociaux d'une nouvelle entreprise se sont les ressources les plus importantes et particulièrement les contacts sociaux de l'entrepreneur sont souvent les principaux éléments stratégiques qui sont en mesure d'améliorer le développement de nouvelles entreprises.

Les principaux résultats de cette étude sont premièrement, le capital social et la croissance économique sont significativement et positivement corrélés, d'autre part, un niveau élevé de capital social a aussi un effet indirect sur la croissance économique par son effet sur l'activité entrepreneuriale. Ainsi, cet article se propose d'élaborer des éléments de réponses théoriques et empiriques à l'effet d'un capital social adéquat sur le renforcement de l'activité entrepreneuriale qui aurait des effets positifs sur l'investissement et la croissance économique.

Using the Concept of Customer Life - Time Value for Internal Customers of Insurance Market

Michael Hanzelka, Technical University in Brno, Faculty of Business, Department of Management, Kolejní 2906/4, 61200 Brno, m.hanzelka@volny.cz

Abstract

Purpose of the article: The aim of this work is to focus primarily on the methodology for internal use CLV customers to create new scientific knowledge in the area of quantifying costs and benefits of internal customers, ie. Employees and partners in a particular market segment. Like external customers (markets) as well as internal customers express their behavior and demeanor greater or lesser affection, in the first case and to mark the latter case the employer. **Methodology/methods:** Therefore, the modeling of CLV for internal customers will require a qualified prediction and quantification of a wide range of both Hard and Soft items and its conversion to a valid pointer.
Scientific aim: The scientific aim is to create new knowledge in methods of evaluating internal customers. In terms of strategic management is an area identifying business value, not only by the value of external customers, but also by the value of internal customers.**Findings:** CLV calculations and methods practiced on external customers, can be used for internal customers of the company as a valid economic indicator, which expresses the extent to which, when using the Hard and Soft HR operations, the company pays an employee in the context of lifelong, union employees with the company.**Conclusions:** CLV model for internal customers will be based on the primary, CBA analysis for obtaining input data that will be used for modeling a modified CLV. The results of the model determines the maximum amount of the discounted average cost of acquisition and retention of internal customers as part of their life cycle in the company.

Keywords: Customer life time value, internal customer, internal marketing communication, proactive, reactive, Cost-benefit analysis.

Critical evaluation of the state of knowledge in the field of research topic

Utilization Concept Customer Lifetime Value (CLV) in Strategic Marketing companies described in (Hanzelka, 2014, Kumar, 2008). Each company performs economic policy objectives through its organizational structure, level of technology and proactive utilization trends in scientific - technical development, which will ensure their economic growth. External customer is the enterprise resource performance and profitability, is the bearer requirements and needs and creator of loyal customer groups. For external customers can be categorized as CLV CLV-OUT. CLV-OUT can be modified for internal marketing companies operating in the insurance market. These are mainly insurance companies, as described in (Hanzelka, 2015). Internal customer helps create production, is the holder of invention and co-creator of the corporate culture of the company. For internal clients is described analogous method for determining the value of internal customer CLV-IN as described in (Hanzelka, 2015). Simultaneously, in the performance of the pilot study was verified hypothesis H0. Calculations and CLV method, practiced on external customers, can be used for internal customers of the company as a valid economic indicator that expresses the extent to which, in the use of Hard and Soft HR operations, the company pays an employee in the context of lifelong, union employees to the company. This pilot study was conducted on a small sample of respondents, yet showed that the value of internal customers is an important variable contributing to the value of the whole company. In the preliminary method was used CBA (Cost Benefit Analysis). CBA method applied to the project monitoring one insurance agent (IA) in the Allianz brings the following conclusions:

- CBA method can be delegated regarded as a form of CLV-IN to determine the value of internal customers in our case IA.

- For calculating the NPV = 1 616 USD, 32 821 CZK value can be internal customer thus set in relation to one average customer.

- From the IRR calculation follows a simple conclusion. The IRR is higher, the project is beneficial, in a metaphorical sense it is a hassle-free return on the project. It is possible to determine the value that brings an experienced IA to Allianz if we assume that the average experienced IA has in its customer portfolio of 500 customers. We conclude that the total value of the internal customer is 80 800 USD ie. 16.410.480 CZK.

The aim of the planned research is focusing on the methodology of using CLV-IN for internal customers and to create new scientific knowledge in the field of quantifying the costs and benefits of internal customers, ie. employees and collaborators of the insurance market segment. Similarly, as external customers (markets) and internal customers (creative force) expressed their behavior and demeanor more or less affection, in the first case to the brand, and in the latter case to the employer. The methodology described below CLV-IN will be verified upcoming research in the field of insurance, respectively. advisory market. Consulting market is focused on the broader area of concern: insurance, finance and investment. IA, in this case, changes to the financial adviser FA.

The current state of the topic

From the perspective of the proposed study on the topic: Using the concept of Customer Life-time value (CLV) in strategic management of companies, it is necessary to describe the importance of metrics CLV-IN as a method for determining success factors.
For this consideration we start from the belief that the success of the company stands for value creation in the behavioral approach is about creating a common interest, which is profit at the intersection of three interest groups, companies, internal customers, external customers. The following Fig. 1 demonstrated this concept of success:

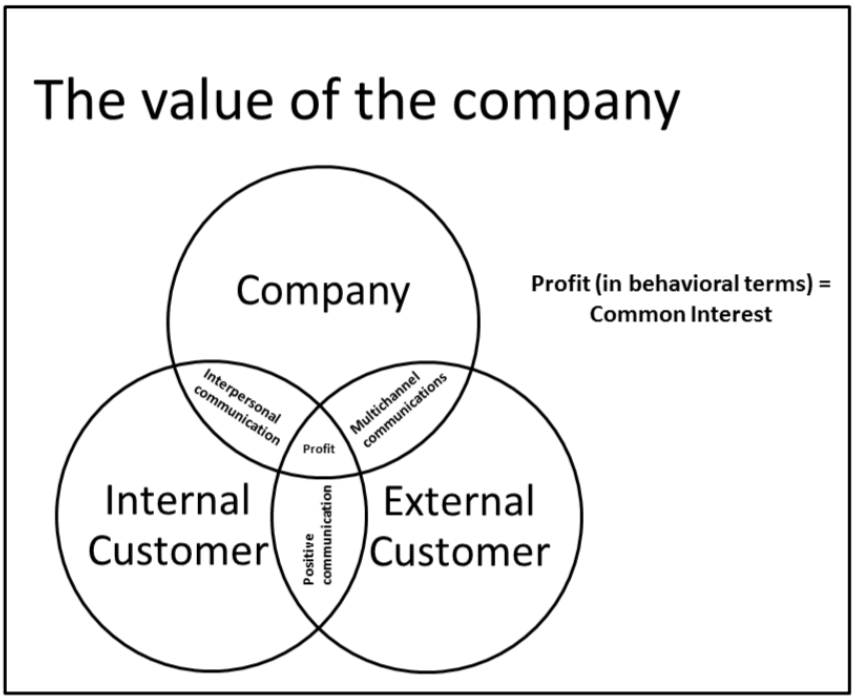

Fig. 1: the companies in the behavioral sense (Hanzelka, 2012)

CLV-IN

rom the perspective of contemporary theories CLV-OUT is an internal customer is the most important article profitability of the company and is considered an asset (Kumar, 2008). CLV-OUT as a metric substantial portion of corporate assets is based on discounted lifetime value that the customer is able to bring enterprise. Very similar to this is in the company's internal marketing strategy. It is based on a simplified things, product or service and the people (employees). Here, only the employee is capable of emotional approach to the product or service to a customer. From the microeconomic studies is included in employee liabilities and firm for him must have resources in the form of working capital. It is, however, only one point of view, because the employee is the primary creator of consumer value (products and services) and fed into the company's customers. CLV-IN as a metric of corporate assets is based on the discounted value of life, which is an internal customer enterprise can bring.

Analogical model CLV

Analogical model metrics CLV-OUT in literature referred to as CLV will be based on linking cost-benefit analysis (CBA Cost Benefit Analysis) to describe the theory CLV-OUT. The project determining CLV-IN internal customers in a particular market segment can be divided into two parts:
1) CBA Analysis (Sieber, 2004) internal customers of the insurance market, in other words, insurance agents specific insurance company. Data for this analysis CBA will be obtained partly primary questionnaire survey and by the analysis of secondary research data.
2) connecting the CBA analysis with the calculation of CLV will set CLV-IN internal customers of the insurance market.

Definition CBA

CBA framework is best not contradictory method for the evaluation of projects in the public sphere. The essence consists in quantifying all the positive and negative effects resulting from the project and the resources needed to achieve them, transfer these costs and benefits into cash flows (getting called. Socio-economic flows) and intertemporal aggregation. (Sieber, 2004).
Socio-economic flows, all socio-economic results of the project after deducting all costs of resources incurred during the project life cycle in order to achieve positive results of the project. Because the socio-economic consequences (flows) occur at different times, they need to be aggregated into an intertemporal evaluation indicators:

• Absolute indicator CBA: ENPV - (Economic Net Present Value) is the sum of the discounted net socio-economic flows of the project from the beginning to the end of its life.

• Relative indicators CBA: ENPV / I (version socioeconomic index of profitability) EIRR (socioeconomic IRR) or B / C Ratio (Benefit-Costs Ratio - the ratio of the sum of the discounted benefits of the project to the discounted sum of project costs), (Siber, P. 2004).

Theory calculation of CLV-IN

CBA allows you to determine the benefit of the socio-economic flows. CLV contrary predictive of direct costs, acquisition costs and retention costs to maintain client. From this structure can be defined by a mathematical expression CLV-IN:

$$CLV-IN_i = ENPV_i - C_i * \sum_{i=0}^{T}\left[\frac{r^t}{(1+d)^t}\right] - M * \sum_{i=0}^{T}\left[\frac{r^{i-t}}{(1+d)^t}\right] \qquad (1)$$

wherein:
NPV - (Economic Net Present Value) is the sum of the discounted net socio-economic flows of the project from the beginning to the end of its life.
C - direct costs of internal customer
r - sustainability (Churn)
d - discount rate
M - maintenance (retention) costs
T - scheduled time

Methods parameterisation of inputs CLV-IN

Calculation method:
Determination of elementary input parameters - preliminary research, based on the survey for financial advisors FA, in order to determine the following input indicators (Hanzelka, 2015):

- The volume of premium trash FA - cash flow
- The volume of premiums for Cross-selling FA - cash flow
- Loyalty FA – index
- Participation in the management FA – index
- Cancellations past shops FA - cash flow
- Quality of service FA – index
- Level of education FA – index
- Incentives for the FA - cash flow
- Commissions for the FA - cash flow
- Commissions for caring for FA - cash flow
- Acquisition costs for acquiring new FA - cash flow
- Costs for retention to maintain the acquired FA - cash flow

Methods of assessment CLV-IN

Methodology enable CLV-IN parameters, and convert the price of internal customer into a single indicator expressed through cash flow. This can determine the profitability of the company's internal customer. Profitability internal customer is none other than the determination of the indicators of whether the enterprise's internal customer pays (Hanzelka, 2015).

The draft research process

CLV method can rightly use to companies that strictly segment the customers. Achieves a more accurate allocation of investments in individual customer segments and better differentiation of costs incurred for multichannel marketing (Kumar, 2010). Fig. 2 is expressed dependence CLV marginal impact marketing communication.

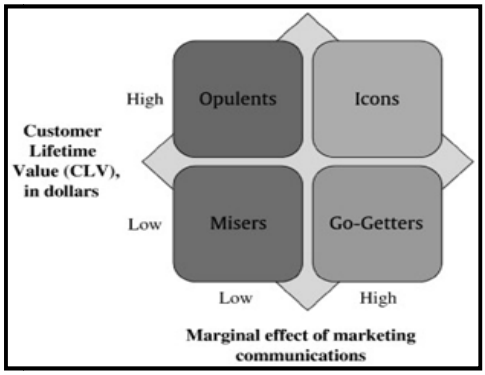

Fig. 2 : Customer segmentation in the CLV and a marginal effect Marketing Communications, (Kumar, 2010).

From Fig. 2. segmentation obvious cost incurred in individual tourism segment to optimize the effects of marketing communications. Adjust segmentation external customers by Fig. 2, a similar model for internal customers in selected segments of the labor market. This segment of the insurance market and the market for financial advice. Specify who the market segment of the insurance market and counseling internal customer. It is an insurance consultant, respertive financial advisor, as executive component, which brings insurer (brokers) income. Internal communication insurer or broker to such Executive Branch can be considered internal marketing communication that is both multi-channel and also is in many ways very similar to the marketing communication that is intended to external customers. Internal customers in the insurance and financial counseling insurer (brokerage) company primarily motivated from three perspectives: financially, technically and professionally. Let's look at a specific transformation Fig. 2, according to the CLV internal customers in the insurance market guidance on marginal effects of internal marketing communication shown in Fig. 3 (Hanzelka, 2015).

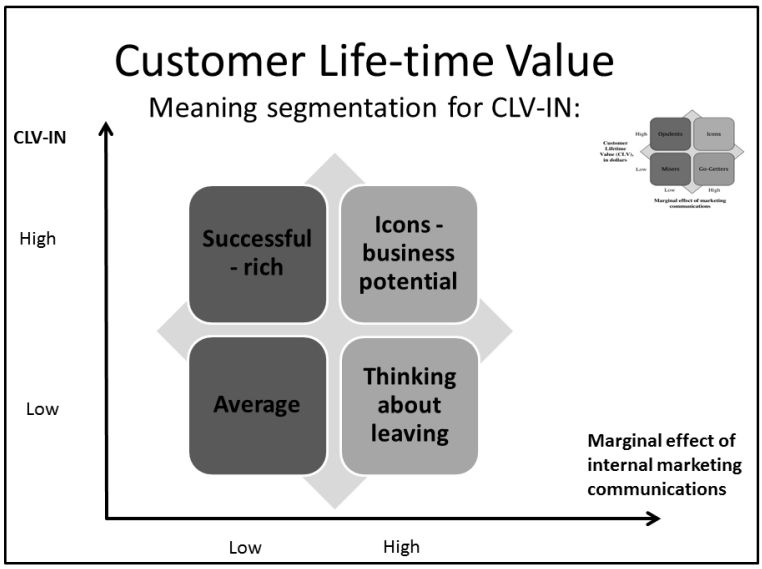

Fig. 3 : Segmentation internal customers in CLV-IN depending on the peripheral effects Internal marketing communications.

Corporate strategy

Part of the corporate strategy are sub-strategies of individual areas of business management. These include the following strategies: Manufacturing Strategy, HR Strategy, Information Strategy, Business Strategy, Marketing Strategy, Financial Strategy, outer and inner value strategy, to which undoubtedly CLV metric as a tool belongs (Collis, J. Hussey, R., 2009). Value strategies are all about sharing values (assets) by which on the one hand consist of external customers, such as customers and on the other internal customers as employees, creators of values. From the perspective of contemporary theories CLV-OUT is the most important link external customer profitability of the company and is considered an asset. (Kumar, V., 2006). Same goes for the corporate strategy. It is based on a simplified things, product or service and the people (employees). Here, only the employee is capable of emotional approach to the product or service to a customer.

Investigated area

Surveyed region is a segment of the insurance market and financial advisory services to internal customers as insurance advisors and financial advisors. Such an internal customer has for internal distribution of insurance companies and consulting firms exceptional value. It's a powerful business component with the potential to acquire new customers, but also with the potential for retention of existing customers, (Hanzelka, 2014). Insurance consultant as an internal customer requires extraordinary care in the field of career development, training, internal marketing communication, motivation and stimulation, financial evaluation, company benefits, comprehensive value proposition. These are the basic items that should be quantified so that they can be expressed in terms of cash flow. Some are at first glance Hard as e.g. monetary values and benefits, but most of them are called. Soft e.g. motivation proferní growth, and the like. Therefore, for the quantification of these Soft parameters is offered to use a well developed theory of costs and benefits (CBA) (Hanzelka, 2015). The thing is, from the outset to look at internal customer acquisition, as at the start of the project, the cycle may coincide with the life cycle of the company. Therefore, the internal customer can be connected with the life cycle of the company and, by analogy, it is possible to express the value of using CLV. To this CLV distinguish them from the current one of the conventional CLV for external customers, we talk about the so-called. Modified CLV (CLV-IN). Analogous modified CLV model is based on linking cost-benefit analysis (CBA Cost Benefit Analysis) to describe the theory CLV. The project determining CLV internal customers in a particular market segment can be divided into two parts (Hanzelka, 2015):

1) CBA Analysis (Sieber, 2004) internal customers of the insurance market and the market for financial advisors), in other words, insurance advisers particular insurance or financial advisors specific brokerage company. Data for this analysis CBA will be obtained partly primary questionnaire survey and by the analysis of secondary research data.
2) Outputs of CBA analysis used as inputs for the calculation of CLV internal customer-defined market segment.

Used research methods

To create a de facto methodology for determining CLV-IN internal customers start from the following assumptions (Hanzelka, 2005):

1) There A set of corporate strategy with important moments in conjunction individual areas of business management.
2) Determination of the areas examined internal customers within a segment of the insurance market and the financial market.
3) Creating a model analogous to the theory of costs and benefits under the sub-project personnel to obtain and maintain internal customers. This theory seems to be a good means to quantify incremental parameters for determining the CLV IN for internal customers, because it is a systematic

process successfully applicable to any project. The result is quantifiable cash flows.
4) Description of the current theories CLV used for external customers.
5) Description analogous modified CLV model for internal customers.

Model research

Distribution of research:

1) The primary survey to obtain predominantly Soft data for subsequent quantification. Is primarily about the motivation and loyalty, which can not be directly quantified. Quantification will be preceded by a qualitative assessment questionnaire.

2) Secondary research directly quantifiable costs and benefits such as operating systems and affiliate companies in the reporting segment.
Primary research: primary survey will be carried out in the following steps: Build the source questionnaire (sample questionnaire on a separate page), Development of a specific methodology of treating the resulting investigation using mathematical statistics, awards outputs from the processing and quantification in cash flows. Secondary research: Secondary investigation in the areas of:

- Analysis of the value proposition,
- affiliate career and Regulations product portfolio,
- business model in a defined market segment.

The project determining CLV internal customers in a particular market segment can be divided into two parts:

1) CBA Analysis (Seber, 2004) internal customer reference market. Data for this analysis CBA will be obtained partly primary questionnaire survey and by the analysis of secondary research data.

2) Outputs of CBA analysis used as inputs for the calculation of CLV internal customers of the reference market. Invaluable costs and benefits will be quantified research activity, ie. Soft convert information on Hard outputs. These benefits, which are called. Soft, will quantify indirect methods, using the primary questionnaire (Hanzelka, 2015).

Conclusion

The aim of the research is to focus on the methodology for internal use CLV customers to create new scientific knowledge in the field of quantifying the costs and benefits of internal customers, ie. employees and collaborators of justice in a particular market segment. Like external customers (markets) and internal customers express in their behavior and demeanor more or less affection, in the first case to the brand, and in the latter case an employer (partner). Therefore modeling CLV for the internal customers will require a qualified prediction and quantification of a wide range of both Hard and Soft items and their transfer to a valid pointer. Modeling CLV for the internal customers will be based on primary, CBA analysis for obtaining input data that will be used for modeling the modified CLV. The results of the model determines the average discounted amount of the maximum costs for the acquisition and retention of internal customers within its lifecycle in the company.

Abstract

This paper highlights the international forms of cooperation in research and development for medium enterprises and it is based on the example of an enterprise from Germany. Medium enterprises face more and more difficulties to state a self-maintained position in the context of commercial competition since the modern production techniques, the high-tech large-scale enterprises often favored and the competition growing due to largely saturated markets. When the autonomous growth ceases because of the financial reasons, the only possibility is to merge with other enterprises from research and development field. This paper is based on a literature review from "international cooperation forms" field and on the study of an enterprise from Germany. The aim of this paper is to present different methods of international cooperation and to derive their optimal shape based on a study of an enterprise. To realize this objective, the authors conducted an analysis of an enterprise from electronic industry field in the period of PhD studies.

Keywords: supply chain management, risk management, outsourcing and insourcing

Introduction

The aim of this paper is to highlight the reasons and advantages of cooperation in the international context using the study on an enterprise within R & D cooperation from Germany.

The demand for a international orientation of the enterprise is conducted recently with increasing frequency. Corporate management has always been important to develop a good international strategy of cooperation for companies in the context of globalization and was always a difficult task. A good form of international cooperation, however, was never as important as now. So many things cannot be forecasted, because the development is so unclear, and we are going through a fundamental phase of change.

International cooperation in the context of globalization has the potential to provide significant benefits to all participants, particularly if managed well. It is common knowledge that international cooperation has the potential to reduce a partner's costs and so they are more efficient for all parties.

The opening of global market offers to companies expansive opportunities for activities (Brandstetter, 2007). The increasing competition, intensive trade and increasing international mobility on internal market, are leading to an enhanced pressure. This pressure is forcing local enterprises to adapt themselves.

The increasing constraints for internationalization of various companies make it clear that the nature and extent of their internationalization activities are afflicted with very large gaps.

By analyzing the companies' current market situation we may conclude that the internationalization of companies is well advanced.

Literature review

Cooperation, from the Latin "cooperatio" (cooperation, collaboration), is the interaction between two or more individuals, persons or systems, particularly on economic or political basis. This work considers begins from cooperation between companies; therefore the main focus lies on business cooperation. In most cases it is about the cooperation of two or more companies for increasing their common competitiveness (Wöhe, 2012). The literature addresses two main criteria (Becker et al., 2005):

- Maintaining the economic and legal independence of enterprises
- Coordination and implementation of joint activities

For the implementation, the participants of such network cooperation are using shared resources and expertise. The alternative is to ensure the same performance through own forces by building up resources or by acquisition on the free market. In this respect, the business cooperation can be considered as an alternative form of organization, which occupies an intermediate position between the market and hierarchy, meaning it stands between contractual regulated and over hierarchy controlled cooperation (Müller, 2003). In Becker's vision (2005) the continuously cooperation in market-hierarchy can be represented so:

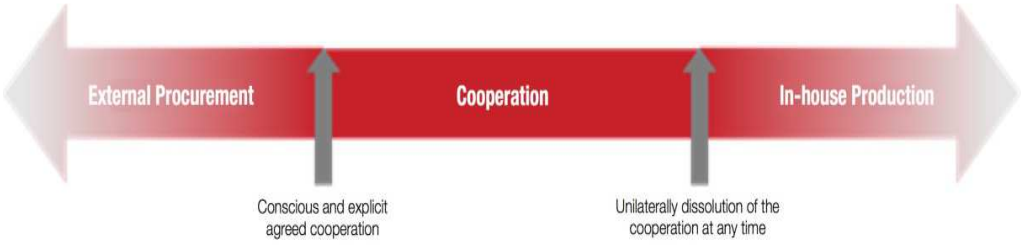

Fig. 1: The Continuously Cooperation In Market-Hierarchy

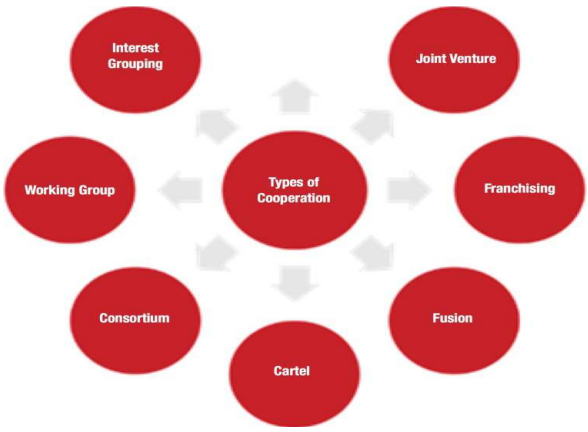

Fig. 2: Types of Cooperation

The figure 2 presents the different types of cooperation.

Each type of cooperation is detailed in the table below:

Table 1: Types of Cooperation

Types of cooperation	
Social group/Interest group: A social group is composed of few or more enterprises which set the goal of enforcing common interests. This form of cooperation is usually controlled by a simple contract and is headed by a chairman employed for this purpose. A classic example is the employer representative (Hendrik, 2008).	**Strategic Alliance:** Strategic alliances, often temporary interrelations (often horizontal) between companies in the same industry whose action relates to a specific business segment. In this form of cooperation it is about pooling resources to achieve a competitive advantage over competitors.
Working group: Working group is especially common in the construction field and serve more companies in a merger for the joint implementation of a project, for example, a major construction project. This form of cooperation is limited in time and usually occurs as a company constituted under Civil law.	**Joint Venture**: The cooperation model of Joint Venture represents the founding of a legally independent company by two or more legally independent enterprises, wherein the reason for the collaboration is to accomplish certain tasks jointly. The reasons for founding a joint venture, may be the association of capacities, pooling of resources or avoiding duplication of investments.
Foreign Trade Cooperation Foreign trade cooperation could take the form of export or import cooperation. For export cooperation or export association single or multiple delivery tasks are divided among the cooperation's partners. Import or buying cooperatives achieve financial benefits by pooling purchases at national and international procurement markets (Decker, 2002).	**Franchising** Franchising is a collaboration between legally independent franchisors and franchisees, whereby the franchisor is responsible for the tasks of planning, implementation and control of a previously successful operation type. The franchisee, in turn, receives the license, of this concept including the services and products to be distributed according to the existing concept (Büter, 2007).
Cartels Generally, cartels are characterized of existing based on a contract which is suitable to influence the market conditions by restricting competition, whereas legally ineffective according to restriction of competition law (Becker et al., 2005). The companies are connected horizontally and remain legally independent.	**Fusion:** The merger represents the most extreme form of cooperation; as independent companies legally merges into one company under one name. Often, smaller companies are this way taken over by stronger partners.

Research Methodology

To reach this objective, the authors had conducted some interviews with the two managing directors. The interviews are used to identify the reasons for business cooperation and to derive the future type of cooperation.

For giving a better statement of an appropriate international cooperation form, it was made a detailed business analysis on the enterprise studied and were summarized the results in a core competency matrix.

Based on these results and the interviews conducted, the reasons for the cooperation between companies inside of the example company was worked out on the basis of theoretical fundamentals and possible cooperation ways in the field of R & D.

These results lead to the recommendation of the possible business cooperation.

Research Results for International Forms of Cooperation on the Example of the Enterprise Studied

For industrial companies, research and development represents a popular area for cooperation within the strategic alliances cooperation type and therefore an indispensable part of daily work.

To withstand the mentioned pressure of competition and innovation, small and medium-sized enterprises are often forced to close development collaborations.

Attributes of such cooperation initiatives are that the partners participate voluntarily to the cooperation, follow common interests and register economical profits from that specific project (BMWi, 2001).

The collaboration can, but must not, be restricted to a certain time frame or achievement of specific targets.

The analyses undertaken revealed that the grounds for entering cooperation in the R & D area may be completely different. The most important considered targets and opportunities for the Sample

However, the objectives are not clearly separable, but often interconnected and are mutually reinforcing each other.

Table 2: Grounds for R & D Collaborations

Grounds	Targets and Opportunities
Complementarity	Companies are entering a cooperation if own resources are not enough to conduct a sought R&D project. Therefore, resources may be used additive or complementary. At an additive bundling it is about a project which is simply too large and more capacities are needed; whereas, conversely, in the complementary method it is about connecting not existing resources with its own. Thus, an effective implementation of a project can be better realized (Helmke, 2008). The pooling of resources continues to bring scale economies, which may lead to a reduction of variable costs. This advantage is particularly important for small-sized companies. They can implement many projects through the pooling of resources with

	partners (Decker, 2002).
Cost reduction	Companies are urged by the increasing time and cost pressure to a steady reduction of costs. Through resources, procurement, installation and usage of equipment, development and further production, costs are rising in any phase of the innovation process. Basically, cost savings can be realized through economies of scale, economies of scope or learning curve effects, respectively knowledge building. Costly redundancies can be avoided and business processes run more efficiently by integrating information and communication technologies. In addition, double investments are thus avoided and the development costs shared within the cooperation (Decker, 2002).
Time savings	Through cooperation, development initiatives have more human, technical and financial resources and can thus be carried out more quickly and efficiently (Becker et al., 2005). This is a necessary consequence which must be drawn from the trend towards more rapid innovation and technology cycles and shorter product life cycles, while increasing product complexity (Heinz, 2005).
Knowledge gain	The company's internal know-how is one of the most important resources to secure competitive advantage. Within an efficient cooperation, know-how can be exchanged controlled, whereby both parties achieve best results. In this respect collaboration is an opportunity to acquire new knowledge. This is done by the targeted knowledge transfer, yet also by generating expertise. Know-how transfer means that previously existing knowledge of a company is incorporated in the cooperation and the partners acquires this new knowledge. If the associate members are liaising knowledge and experience to new ideas than Innovation Learning takes place (Helmke, 2008). The gain of knowledge in turn leads to cost and time savings and can bring other positive effects, such as quality improvements.
Capacity supplement	A capacity supplement follows a similar pattern as the economies of scope. It means pooling of resources through which larger projects can be realized. Those might be among others, financial capacities or for example, output capacities, equipment or personnel.
Risk reduction	Each R & D project is associated with risk factors. If the costs are shooting up, the developed “passes over the market” or feasibility problems appear, development projects can turn into million graves, which cause the company long term negative consequences. To reduce the threat, the allocation of such risks on several network partners is an effective measure, as at the occurrence of such risk factors the entire cooperation spreads the cost or have enough resources are available to improve or save the project (Schuhmann, 2004) . From a risk management perspective a higher risk means also a higher return, which

	in case of a partner would be cut in half.
Market access facilitation	Market entry and mobility barriers can generally prevent the entry into a new market. Increased capital investment or gain of know-how and technology can overcome these barriers. The missing resources may be provided by cooperation partners and the access to new markets from home or abroad is obtained through business connections. Especially abroad the resident partner can help to overcome commercial barriers. Through partners also knowledge of the new market can more easily be acquired and making the chances of success best improved (Decker, 2002). These new contacts can be strengthened by further successful collaborations which buildup a healthy corporate network (Helmke, 2008).

Within the first step, the results of the study answered the question about the grounds for a business cooperation of the sample company.

Based on the range of occupations, the sample company is more of a specialist - and not a complete range products provider. With its division as controller, image processing and computer systems, the sample company is more application-oriented and less product-oriented.

Since the company is not a technology leader, the sample company uses new technologies in electronics, respectively in the field of microelectronics and image processing for the research and development of the own products.

In order to make statements about the core competencies of the sample company, was developed a core competency matrix.
The results of the conducted interviews and the business analysis are represented below:

Table 3: Core Competence Matrix

Area of competence	Critical skills	Is-situation	2015
1. Product/Project specific competencies	- technological workout, further development and manufacture of existing product solution	+	
	- development and manufacture of new product solutions based on existing or new technologies	+	+
	- maintaining and further development of the technological level	+/0	
2. Market specific skills	- reccognising customer's new needs and development and execute them effectively		
	existing markets	0	+++
	new markets	0/-	
3. Functional abilities	- delivering customer specific top solutions	+	
3.1 Production processes/Departments	- push through high prices	-	
- Development	- offering complete product range	-	
- Distribution	- offering good services	+	
- Technical contract development	- new customer acquistion	-	
- Purchasing and Manufacturing	- offering complete solutions	0	
3.2 Supporting Processes	- delivering system solution	0	++
- Technology	- efficiently manufacturing	0/-	
- Human Ressources	- cost efficiently procuring	0/-	
- Infrastructure (IT, QM, FI)	- using, binding and recruiting highly skilled employees	+/0	
	- fast pay-back from R&D Investments	-	
	- low quality management costs	0	
	- procure new financial resources	-	
4. Cross key topics	- strategical marketing	+/0	
	- product management / V-products	0	
	- first class cost management	-	+++
	- management and control of heterogeneous businesses	-	
	- technological/commercial Project management	0	

Capacity + high developed / 0 medium developed / - low developed

+++ very high ++ high + less high

Looking at the picture more closely, it can be seen that the sample company is aligned technically-technologically and can provide customized solutions in the mid and high-end segment. However, the skills for R&D are not sufficiently pronounced to generate here a great added value for the sample enterprise. This problem is reflected, among other things, by the accepted and sells research contracts without knowing how long will take the development of the appropriate solution. The consequence therefore is that are needed more days for the development, which cannot be charged. This results, in a great financial loss for the sample company, which, in most cases, cannot be retrieved on the sale of the developed product.

From this, can be derived the following strategies for research and development:

Table 4: Objectives for the Research and Development

Goal / Strategy	Example
Cost reduction	Develop cost-optimized product solutions for defined applications or customers
Quality improvement	Develop quality-oriented products for defined applications or customers
System solutions	Deliver system-solutions and not components or modules

Because the sample company of medium-sized companies is too small, for ensuring a cost-optimized R & D business it has to enter into the cooperation area. This way, synergies can be reached which creates added value not only for the Sample Company but are also interesting for the cooperation's partners.

Because only this way can the cooperation's partners withstand the cost, innovation and market competency pressure (Becker et al., 2005). Through the one international cooperation form new funding can also be obtained, which initially takes the cost pressures of the new research and development projects. The international development cooperation have also the advantage that thereby new distribution channels can be developed with which new markets are opening up to.

The figure below presents the market entry forms, after (Gabler, 2015):

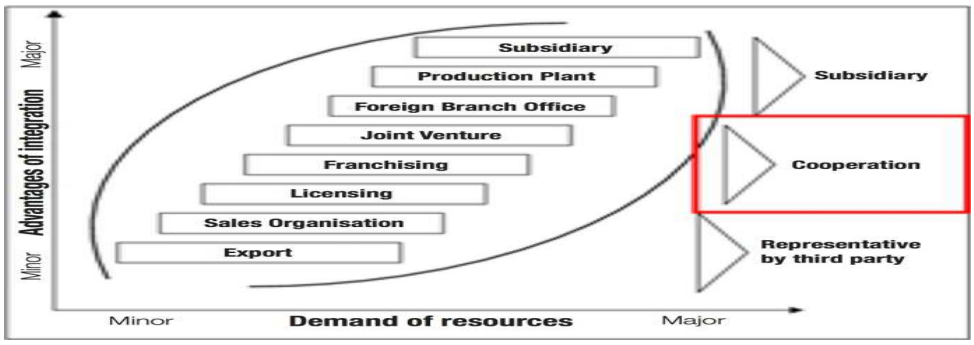

Fig.3: Market Entry Forms

Another reason for entering into collaborations is that incentives are not made as prior to the extent of the country. Thus, the Sample Company is formally compelled as a medium-sized company to cooperation. Incentives are critical, especially since the projects are often lost and the actual research and development costs are not covered and completely supported by the Sample Company.

The company tried to be successful with various cooperation types. Therefore, company has strategic partnerships in the areas of customer and supplier relationship that were used for entering new markets and increasing sales. In addition, this type of co-operation is used to strengthen customer relationships and to obtain access to new contacts and trade fairs.

In the past, the enterprise studied has cooperate with another company, which is commercially distribution-oriented. However, cooperation lasted only one year and was dissolved by the partner, due to commercial reasons. The aim of that company was to learn about the Sample Company out from the cooperation and buy it cheaper afterwards. Finally, the Sample Company had a whole range of incentive projects, which have not brought the desired long-term success.

Just this past cooperation example shows that the Sample Company has always had a weak partner and the last one was focusing only on its own advantage.
Considering the problems in the past, which have occurred in different collaborations of the Sample Company, it becomes quickly clear that the company must take a different approach to reach long-term success in international markets. A strategic alliance in the field of research and development (R & D cooperation) may be for the Sample Company a good option in order to step abroad and continuing to be international. Through this type of cooperation, it becomes possible for the Sample Company to remain legally independent and still having the opportunity to carry out collectively certain tasks, especially in the area of research and development. In this context, it is of secondary importance whether the strategic alliance in the field of research and development, is unlimited or made only for a specific research project.

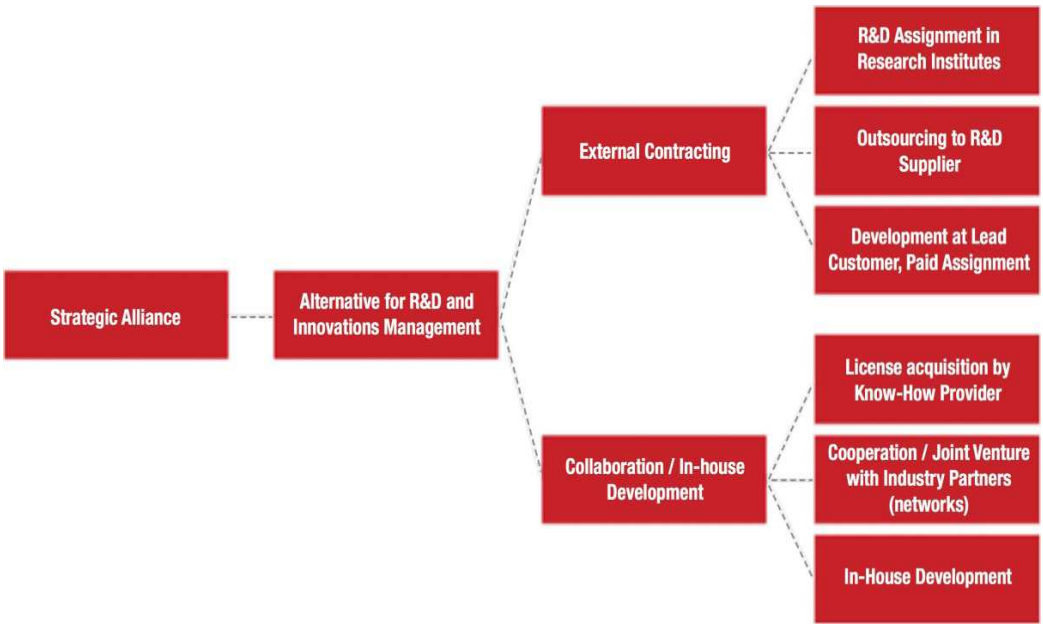

Fig.4: Example of Cooperation Types in the Enterprise Studied

Conclusion

The results of the research undertaken showed that regardless of size and industry cooperation, in research and development companies is included within the daily operations. While earlier research was done by individual scientists with pencil and paper and carried out in inexpensive laboratory equipment, nowadays, it is necessary to cope with the immense costs of research that can only be worn by several companies together.

Today we speak about an European economy, where companies operate mainly international. The interaction between national and collaborative funding of the EU Member States can lay the foundations for a European dimension of cooperation in research and development.

Cooperation is becoming more complex, dynamic and multi-faceted. The cooperative abilities of both large and small-sized companies have become the main criteria for a long-term success. This is accompanied by process and IT standards, which are the basis for an effective collaboration between several enterprises. Reports and comments from all research-intensive sectors show that it needs a greater cooperation. Classical approaches of "competitive markets" are reconsidered and increasingly efforts are sought in the context of cooperation and competition in complex "co-petition" networks. A prevailing example in literature and the news is the automotive industry.

Equally, similar surveys of companies in various industries are documenting that cooperation are carried out in all areas and gain even more importance in the future development. By standardizing and optimizing cooperation from process perspective by the aid of modern communication and organization tools, efficiency and effectiveness can be increased, thus leading on ensuring company's success for the cooperation partners, and on the advancement of national and international science.

Research results showed that the enterprise studied has illustrated the opportunities given by a research and development cooperation. The success is primarily given by the grounds of this form of cooperation, through which, medium-sized companies competitively remain. R & D cooperation can thus serve as a successful alternative collaboration for remaining successfully in the market. For the Sample Company, an R & D cooperation is a good way of growing internationally. For this reason it is recommended to implement R & D cooperation in the context of a market entry strategy as of the Sample Company to permanently be successful on the international market.

Abstract

The aim of this study was to present new mediating and moderating variables in the relationship between online advertising and purchase intention as well as visiting the store. Therefore, a qualitative study of 17 Tunisian Internet users was conducted. The results show that the change in lifestyle and the willingness to visit the store are mediating variables between these consequences and electronic advertising (purchase intention and visiting the store). Furthermore, the involvement with the product is the moderating variable between e-advertising and change in lifestyle, including willingness to visit the store.

Keywords: online advertising; mediating variables**;** moderating variables

Introduction

La publicité électronique est une activité moderne. Elle représente, d'une part, « le pilier commercial du réseau Internet d'aujourd'hui »[1] et d'autre part, un moyen idéal pour « assurer la promotion des services ou produits proposés dans un site web »[2].

Dans ce cadre, les dépenses de la publicité en ligne vont dépasser 40 milliards de dollars en 2017[3] aux Etats Unis et en Europe. En Tunisie, les dépenses publicitaires sur Internet ont passé de 1,6 million de dinars en 2007 à 3,8 millions en 2012[4]. C'est un outil en pleine progression où les recherches académiques autour de cette variable sont très importantes. En effet, l'e-publicité permet l'accroissement de la mémorisation (Tanveer et Changhyun, 2014), l'inconscient (Yoo, 2008), l'attitude envers la marque (Li, Daugherty et Biocca, 2002), l'attitude envers la publicité, l'attention, les intentions d'achat en ligne (Hamborg, Bruns, Ollermann et Kaspar, 2012) et l'augmentation du taux de clics (Aksakallý, 2012).

[4]´Spécial Open Sigma–Ettounsiya Tv accapare 23,5% des investissements publicitaires en Tunisie´ (2013), [Online], [Retrieved Mai 5, 2015], www.businessnews.com.tn

Il semble que les managers auront tendance à mettre l'accent sur l'augmentation des investissements dans le marketing électronique et de l'e-publicité. Il paraît que les performances d'e-commerce ne suivent pas d'égal à l'importance des dépenses de la publicité en ligne. Selon une étude de l'agence Leadformance, 82% des ventes se réalisent à partir des points de ventes physiques contre 13% à partir du web[5]. En Tunisie, les ventes électroniques sont faibles ou presque inexistantes car le commerce électronique peine encore et le consommateur n'a pas encore l'habitude d'acheter en ligne.

Ces données nous renseignent sur la remarque que la communication en ligne n'implique pas seulement une augmentation des achats électroniques, mais celle-ci peut accroître les ventes dans les magasins. Par exemple, en France, un nombre important de «*cyberacheteurs*» (environs 64%) pensent qu'il est mieux d'enlever le produit au point de vente après un achat à partir du site Web de l'entreprise[6]. En 2020, 53% des achats en point de vente en Europe comporteront des recherches sur Web[7]. Par conséquent, nous préconisons d'étudier les conséquences de l'e-communication dans le contexte off ligne. En tenant compte de ce qui est précédemment cité, les recherches se sont notamment focalisées sur l'étude des conséquences de cette notion seulement dans le contexte virtuel. Aucune recherche n'a essayé de proposer l'impact de celle-ci sur le comportement off ligne du client. Par conséquent, en se basant sur la théorie de la hiérarchie des effets, la question de recherche à laquelle nous essayerons de répondre est la suivante: Quel est l'effet de la publicité en ligne sur l'intention d'achat off ligne de l'internaute et la visite du point de vente ?

L'originalité de cette étude réside également dans la prise en compte des nouvelles variables médiatrices qui sont « le changement du mode de vie » et « la disposition à visiter le magasin ». Les variables médiatrices identifiées dans la littérature, sont les attitudes (Zaichkowsky, 1994; Wei, Jerome et Shan, 2010). La variable modératrice dans ce nouveau modèle est « l'implication avec le produit ». Les variables modératrices présentées dans la littérature, sont « le genre et l'expérience » (Sun, Lim, Jiang, Peng et Chen, 2010). Pour répondre à cette problématique, une étude qualitative est réalisée auprès de 17 internautes afin de préciser les propositions de la recherche et les échelles de mesure (Giannelloni et Vernette, 2012). Dans les prochaines lignes, les résultats de cette enquête seront exposés.

La publicité en ligne

Hanafizadeh et al (2012) ont mentionné que la publicité en ligne est « *Un processus basé sur l'Internet par lequel l'annonceur communique, interagit et persuade les internautes afin de promouvoir leurs préférences d'une manière plus personnalisée et de diminuer le temps nécessaire pour prendre une décision d'achat* ». Dans ce contexte, Kuisma et al (2010) ont montré qu'il existe trois caractéristiques principales de la publicité en ligne qui sont : l'animation, le format et le contenu. Ainsi, Yoo et al (2005) ont prouvé que l'animation est le facteur le plus déterminant pour l'efficacité de la publicité électronique.

Wang et al (2007) ont préconisé que le construit **contenu** réfère à la mesure dans laquelle le message publicitaire inclut un ensemble d'informations intéressantes pour l'internaute. C'est aussi une composante très intéressante puisque la publicité en général a comme objectif principal d'informer le client. Le troisième construit de la publicité c'est **le format**. Cette dimension comporte

la taille, les couleurs et les images. Ceci est relié à l'existence de différents types de publicité en ligne. Wei et al (2010) ont montré que chaque type a son pouvoir d'attirer l'internaute.

L'étude qualitative

Dans le livre de Giannelloni et al (2012), pour la mise en œuvre de l'étude sur terrain, le suivi de l'ensemble des étapes bien définies est réalisé. Tout d'abord, il faut choisir la méthode de recueil des données. L'outil convenable dans cette recherche est l'entretien individuel semi-directif. Ceci revient à la raison qu'il se présente comme l'outil le plus utilisé et privilégié par les chercheurs en gestion et plus particulièrement en marketing. Pour réaliser cette forme d'entretien, il faut élaborer, ainsi, un guide d'entretien (deuxième étape). La troisième étape de l'étude qualitative, c'est la précision de l'échantillon. Dans cette recherche, le nombre des entretiens retenus est de dix-sept en tenant compte du principe de saturation. En effet, la diversification dans le profil des répondants portera sur les critères suivants : l'âge, le genre et la catégorie socioprofessionnelle. Le seul trait commun que doit avoir chaque participant est qu'il est utilisateur d'Internet. Enfin, la dernière étape, c'est le choix de la méthode d'analyse des données. La méthode la plus appropriée pour cette recherche est celle de l'analyse de contenu. Les étapes de cette analyse sont les suivantes : la transcription des entretiens, choix et précision de l'unité de l'analyse, construction de la grille, analyse thématique, quantification et élaboration d'un rapport de synthèse.

Les propositions de la recherche

Les conséquences de l'e-publicité seront présentées dans les titres suivants.

Le changement du mode de vie

Wind et al (1974) ont prouvé que, en marketing, la variable mode de vie est un antécédent principal qui permet d'expliquer les décisions du client en termes de choix du produit à acheter, le choix de la marque et le choix du média de communication. Ainsi, Valette-Florence (1986) a défini cette notion comme *« la résultante globale du système de valeurs d'un individu, de ses attitudes et activités et de son mode de consommation ».*

Dans le cadre de cette recherche, nous allons proposer une nouvelle variable nommée « changement du mode de vie ». Samuelsen (2006) et Valette-Florence (1986) ont montré que ce choix est basé sur la remarque que le mode de vie est une variable instable et en évolution permanente à cause de l'existence d'un ensemble de construits prédicteurs (la culture, l'exposition aux médias,…). Ainsi, Molino (1998) a défini la notion de changement comme « *toute transformation observable dans le temps, qui affecte, d'une manière qui ne soit que provisoire ou éphémère, la structure ou le fonctionnement de l'organisation sociale d'une collectivité donnée et modifie le cours de son histoire* ».

A l'aide de ces arguments et les résultats de l'étude qualitative, la variable changement du mode de vie peut être défini comme suit : « ***c'est la volonté d'une personne ou groupe d'individus à faire évoluer la manière de vivre, d'être et de penser*** ». Ainsi, les professionnels montrent que « *dans le commerce et dans la publicité, un mode de vie devient une cible marketing, que les commerciaux tentent de cibler pour s'approcher au mieux des besoins et des envies de consommation de cette population particulière »*[8].

Les résultats de l'étude qualitative prouvent que l'importance de l'e-publicité pour l'internaute, peut l'amener à prendre la décision de changer et améliorer sa vie en acquérant le produit ou service en question. Par exemple, « *Oui, en m'intéressant à la publicité je veux changer et avoir le nouveau produit. Je veux être à la mode si le produit me plait et avoir toujours la possibilité de convaincre les autres dans mes discussions après l'utilisation » : participant 3.* Donc, **La publicité en ligne s'avère**

[8]Mode de vie (2013), [Online], [Retrieved Janvier 13, 2016], fr.wikipedia.org

engendrer un effet sur la volonté consommateur de changer afin d'améliorer son mode de vie quotidienne.

La fréquentation du point de vente

Lombart et al (2005) ont précisé que le consommateur considère un point de vente (magasin) comme un lieu où il peut vivre plusieurs expériences. En fait, Filser (2000) a montré que « *le point de vente n'est plus uniquement envisagé comme un lieu où le consommateur «va faire ses courses», mais également comme un lieu de vie sociale, de découverte, de promenade et de détente*». De même, Lombart (2004) a bien précisé les différents modes de fréquentation des magasins. Ils sont de l'ordre de quatre : le butinage, le magasinage, le shopping et la lèche-vitrine. Le butinage représente la visite d'un magasin pour passer du temps et réaliser une nouvelle expérience. Le shopping représente une activité de visite d'un ensemble de magasins où le consommateur a pris d'avance la décision d'acheter un produit bien défini. Le magasinage représente la visite du magasin pour la collecte de l'information. Le lèche-vitrine est une activité de la visite du magasin sans la nécessité d'entrer à l'espace concernée.

Dans ce contexte, Valette-Florence (1986) a montré que le mode de vie est un critère pour élaborer leurs stratégies de distribution. En fait, le consommateur fréquente et choisit un magasin bien déterminé selon son mode de vie. Par conséquent, cette forte corrélation entre le mode de vie et la fréquentation du point de vente, nous permet de mettre en évidence l'existence d'une relation entre le changement du mode de vie et la décision de visiter un magasin. Il est utile de noter que les participants ont montré que leur décision de visiter le magasin est liée à leur volonté de changer leurs modes de vie et satisfaire leurs besoins. « *J'ai réalisé des visites au magasin pour satisfaire mon besoin d'avoir le nouveau produit et vérifier les informations présentées dans la publicité » : participant 6.* Donc, **Le changement du mode de vie des consommateurs influence la visite du magasin, tout dépend de la réponse à l'exposition au message publicitaire.**

La disposition à visiter le magasin

House et al (1996) ont défini la disposition comme « *des tendances pour répondre à des situations, ou des catégories de situations, d'une manière particulière prédéterminée* ». Taylor (1979) a montré que, en marketing, la disposition a constitué souvent une variable prédictive et explicative du comportement du consommateur. Grace (2005) a mentionné que, généralement, la disposition est un antécédent de la préférence de la marque, satisfaction, intention d'achat, bouche à oreille,….

Comme précédemment indiqué, la variété modes de fréquentation des points peut s'expliquer par des différences de comportement. House et al (1996) ont prouvé que cette divergence comportementale peut indiquer qu'il existe un groupe d'individus peut prendre facilement la décision de visiter le magasin alors que d'autres individus ne peuvent pas. Tout dépend des tendances particulières des uns et des autres à s'investir dans les activités de visite des magasins. Ainsi, nous pouvons considérer que certaines personnes sont simplement prédisposées à prendre cette décision alors que d'autres le sont moins ou ne le sont pas. Nous pouvons alors proposer de définir la disposition à visiter le point de vente comme suit: « ***la disposition à visiter le magasin est définie comme la tendance du consommateur de réaliser une action de visite du point de vente afin de réaliser un objectif bien déterminé***».

Dans ce contexte, en tenant compte des résultats de l'étude qualitative, plus les internautes font attention à l'e-publicité et plus elle suscite leurs intérêts, plus ils auront une prédisposition favorable à réaliser une visite au point de vente. Cette visite sera essentielle pour confirmer l'information présentée dans la publicité et procéder éventuellement à un acte d'achat. Par exemple : « *J'ai la volonté de se diriger vers les points de vente parce que je suis convaincu par la publicité » : répondant 4.* Ainsi, **la publicité en ligne semble influencer la disposition du consommateur à visiter le magasin (ou le point de vente) afin de vérifier le contenu informationnel dans cette communication.**

D'autre part, la disposition à visiter le magasin peut constituer également un antécédent de la décision de visite. L'examen de la revue de la littérature existante nous révèle qu'aucune recherche n'a confirmé ou infirmé cette relation. Néanmoins, Taylor (1979) a indiqué que la disposition environnementale, au même titre que les traits de personnalité, oriente le consommateur à réaliser certaines réactions dans sa vie quotidienne. Craik et al (1977; p.147) ont proposé que «*les dispositions environnementales dénotent des variations individuelles dans les réactions d'un consommateur, qui touchent son environnement physique quotidien*». L'environnement physique fait référence à la maison choisie, centre commercial visité, etc. Ainsi, cette disposition est un déterminant du comportement d'un individu dans le choix d'un point de vente précis et elle influence son attitude et son mode de fréquentation. En effet, les consommateurs qui sont fortement prédisposés sont ceux qui se comportent d'une manière récréationnelle et forment des attitudes positives. Par conséquent, nous inspirant de cette théorie, nous pouvons déduire qu'il est possible de proposer une relation entre la décision et la disposition à visiter le magasin respectivement. Cette déduction semble bien se confirme en se basant sur l'étude qualitative. En effet, plus l'internaute a une aptitude favorable vers l'idée de visiter le magasin, plus il prend facilement la décision de s'orienter vers le point de vente pour acheter ou pour réaliser une activité de loisir. Par exemple : « *Je me dirige vers les points de vente car dès le début j'ai l'idée et la volonté de visiter le magasin » : interrogé 7.* Donc, **la disposition à visiter le magasin semble influencer la décision de visiter du consommateur, d'autant que de la propension à visiter ce dernier existe préalablement.**

L'intention d'achat

Belch, et al (2004) ont défini cette variable comme « *la prédisposition du consommateur à acheter une marque ou produit bien identifié* ». Les recherches antérieures montrent que la publicité influence indirectement l'intention d'achat par les attitudes. En fait, le mode de vie est un antécédent des réactions du client comme le choix du produit à acheter et le choix de la marque. Donc, le changement du mode de vie va entraîner chez l'individu la volonté d'acquérir les nouveaux produits permettant de réaliser cette modification dans sa vie individuelle ou sociale. Par conséquent, nous pouvons proposer que le changement du mode de vie puisse avoir un effet sur l'intention d'achat d'un client. En se basant sur les résultats de l'étude qualitative, les personnes qui veulent changer leurs modes de vie et faciliter la réalisation de leurs affaires quotidiennes, ont plus l'intention de réaliser les actions d'achat des produits modernes présentés dans la publicité électronique. Par exemple : « *si la publicité porte sur mon produit préféré, je voudrai acheter le nouveau produit du magasin afin de satisfaire mon besoin » : participant 16.* A partir de ces conclusions, **le changement du mode de vie semble influencer l'intention d'achat du consommateur.**

Egalement, Lombart (2004) a montré que l'existence ou l'absence de l'intention d'achat est une autre cause de l'apparition de ces différents comportements des consommateurs lors de la visite du magasin. Par exemple, l'intention d'achat existe en adoptant le comportement du shopping. En outre, en tenant compte des entretiens menés dans cette recherche, le consommateur qui aura une forte intention d'acheter le produit, prendra la décision de visiter le magasin afin d'acquérir le produit ou service. En se basant sur ces arguments, **l'intention d'achat a un effet positif sur la visite du consommateur au magasin (point de vente).**

La variable modératrice : L'implication envers le produit

Zaichkowsky (1994) a proposé que cette variable est *« la pertinence du produit aux besoins et aux valeurs des consommateurs et d'où l'intérêt pour les informations sur le produit »*. Merabet et al (2014) ont montré que l'implication avec le produit joue un rôle modérateur entre la publicité et ses conséquences comme les attitudes. En d'autres termes, les consommateurs fortement impliqués seront intéressés plus par les publicités. Ils seront capables de mieux recevoir l'information présentée dans le message surtout si elle porte sur une nouveauté. Il est facile pour eux de faire un bon décodage et traiter d'une manière plus convenable l'information car ils connaissent plus les produits et leurs efficacités. Ben Miled–Chérif (2001) a suggéré que ce traitement facile de l'information publicitaire rend ces consommateurs les plus sensibles à modifier leurs attitudes et accroitre les chances de réaliser une décision d'achat. Alors que les clients à faible implication ne s'intéressent que pour les éléments périphériques du message comme la couleur et la musique.

Dans cette recherche, en se basant sur ces arguments et les réponses des participants dans l'étude qualitative, plus les consommateurs sont impliqués, plus ils sont intéressés à l'information présentée dans la publicité sur net. Cet intérêt va les inciter à visiter les magasins afin de voir un échantillon physique du produit. Egalement, il sera très facile d'accepter le changement du mode de vie afin que le client reste utilisateur de son produit préféré. « *Pour moi, je suis très impliqué avec mes produits préférés. Je regarde toutes les publicités présentées sur ces derniers. Bien sûr je veux plus changer avec mon produit préféré et j'aimerai plus visiter le point de vente pour voir le nouvel échantillon » : répondant 3.* Donc, **la relation entre l'exposition à la publicité en ligne et le changement du mode de vie est influencée par l'implication avec le produit.** En outre, **la relation entre l'exposition à la publicité en ligne et la disposition à visiter le magasin est influencée par l'implication avec le produit.**

L'élaboration de l'ensemble de ces propositions va permettre de tracer le modèle de recherche à tester en réalisant des études quantitatives.

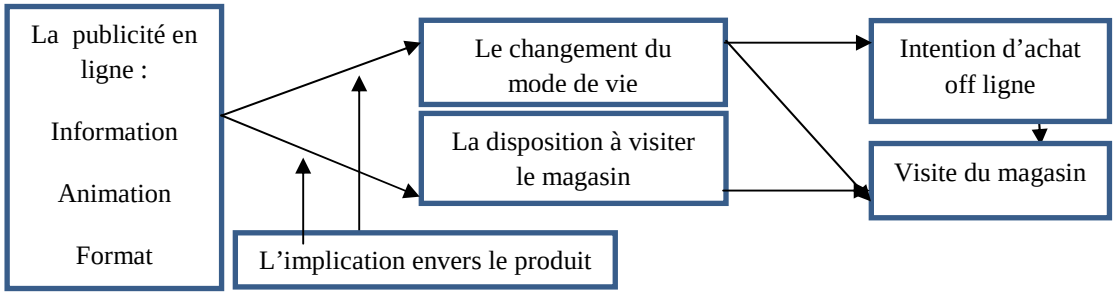

Fig 1 : Le modèle de recherche

Les échelles de mesure

Les différentes échelles de mesures choisies sont synthétisées dans le tableau suivant.

Tableau 1 : Les échelles de mesure des variables étudiées

Construit	Item	Sources
Publicité en ligne	**Information :** Une grande importance est accordée au contenu général de la publicité sur Internet ; Je trouve l'information contenue dans la publicité en ligne adéquate et récente ; L'information contenue dans la publicité en ligne présentée porte sur des nouveautés ; La publicité en ligne communique l'information appropriée pour faire des achats ; L'information contenue dans la publicité en ligne est pertinente car elle m'aide beaucoup dans mes décisions de visiter les sites ; L'information contenue dans la publicité en ligne m'aide à connaître ce que je veux sur le produit ; **Format :** Une grande importance est accordée aux couleurs en surbrillance ;	Dreze et Zufryden (1997) ; Wu, Wei et Chen (2008) et étude qualitative : L'échelle de mesure de Dreze et Zufryden (1997) est utilisée par les chercheurs Wu, Wei et Chen (2008). Pour cette échelle, il y a des items portant sur l'information, sur le format et sur l'animation. Les items générés de l'analyse des entretiens aident a confirmé à propos le choix de cette échelle.

	La publicité en ligne présente un format original dans sa présentation sera très attirant ; La publicité en ligne contenant des couleurs très variées m'attire plus ; Dans la publicité en ligne, les images avec des couleurs bien choisies m'attirent plus ; **Animation :** Une publicité qui contient plusieurs mouvements est plus attirante ; La publicité en ligne est d'autant plus attirante qu'elle contienne des actions d'animations ; Une grande importance est accordée à la conception flash ;	
Changement du mode de vie	**Mode de vie personnel :** Je suis satisfait de mon mode de vie et des produits ou services actuels ; Je n'aime pas trop changer dans ma vie quotidienne et les produits utilisés ; Etre évolué dans ma vie personnelle en utilisant des produits ou services actualisés ; Je n'aime pas la routine dans ma vie ; J'aime changer pour améliorer mes connaissances ; J'aime toujours avoir des produits ou services très modernes ; J'aime le changement dans ma vie personnelle et les nouveautés. **Mode de vie social :** Montrer mon style aux autres ; Changer pour avoir la possibilité de convaincre les autres dans mes discussions après l'utilisation des nouveaux produits ; Avoir les nouveaux produits qui me rendent plus différent des autres ; Je veux être à la mode comme les autres.	Nouvelle échelle résulte de l'étude qualitative : aucune mesure n'est proposée dans la littérature
La visite du magasin	Il est très utile de visiter le magasin après la diffusion de la publicité sur Internet ; je visite automatiquement les points de vente après la diffusion de la publicité sur Internet ; Il est rare que je visite les magasins après la connaissance de la publicité sur Internet ; Je ne réalise pas des visites aux points de vente en tenant compte de la publicité en ligne ;	Nouvelle échelle résulte de l'étude qualitative : La littérature présente des mesures des différents modes de visite. Dans cette recherche, il est nécessaire juste de connaître si le consommateur peut réaliser ou non des visites au point de vente après la diffusion de la publicité en ligne. Une autre solution peut se présenter, il s'agit de construire une échelle à partir des réponses des participants dans l'étude qualitative.
	Après la diffusion de la publicité sur Internet, je réfléchi sérieusement à visiter le magasin ; Après la diffusion de la publicité sur Internet,	Nouvelle échelle résulte de l'étude qualitative : aucune mesure n'est proposée dans la littérature

La disposition à visiter le magasin	je mets en priorité l'idée de visiter le magasin ; Je tends à me diriger vers les points de vente après la connaissance de la publicité électronique ; Après la connaissance de la publicité sur Internet, ma volonté de me diriger vers le point sera plus forte ; En tenant compte de la publicité en ligne, je ne voudrai pas visiter les points de vente ;	
L'intention d'achat	Après avoir visionné la publicité sur Internet, je vais acheter la marque objet de la publicité ; Après avoir visionné la publicité sur Internet, je deviens intéressé à faire un achat du point de vente ; Après avoir visionné la publicité sur Internet, je suis prêt à essayer d'utiliser le produit.	Wu, Wei et Chen (2008) : Les réponses dans l'étude qualitative sont similaires à l'échelle de mesure choisie
L'implication avec le produit	C'est un produit qui compte beaucoup pour moi ; C'est un produit auquel j'accorde une importance particulière ; Je me sens particulièrement attiré(e) par ce produit ; Le seul fait de me renseigner pour en acheter un est un plaisir ; On peut dire que c'est un produit qui m'intéresse ; J'aime particulièrement parler de ce produit.	Strazzieria (1994) : L'avantage de cette échelle est celui de l'exclusion de la notion du risque perçu. De même, elle est utilisée dans des recherches récentes dans le domaine de la publicité.

Conclusion

En rappelant que l'objectif de cette recherche était de déterminer l'effet de la publicité en ligne sur le comportement du consommateur dans le contexte hors ligne, une étude qualitative exploratoire a permis d'identifier quatre conséquences : le changement de mode de vie, la disposition à visiter le magasin, l'intention d'achat et la visite du magasin. Il en ressort de cette étude que les variables changement du mode de vie et la disposition à visiter le magasin (nouveaux construits en termes de définition et échelle de mesure) sont des nouvelles variables médiatrices entre la publicité en ligne et les réactions affectives du consommateur (l'intention d'achat et la visite du magasin). Il s'agit d'une voie future à tester et à valider vu qu'elle n'est pas encore étudiée. En fait, la majorité des recherches antérieures présentent les différentes formes d'attitude (envers la publicité, envers la marque) comme des variables médiatrices. Enfin, il faut confirmer ou infirmer les différentes propositions de recherche élaborées en réalisant une enquête quantitative. Mais, tout d'abord, il est utile et primordiale de vérifier la structure des échelles de mesure présentées en se basant sur le paradigme de Churchill. En fait, il existe des échelles qui sont empruntées de la littérature et d'autres qui sont nouvelles (résultat de l'étude qualitative). Egalement, la réalisation des entretiens de groupe s'avère plus appropriée que les entretiens semi-directifs.

Publicité Rhétorique Versus Non Rhétorique : Quel Effet Sur L'imagerie Mentale ?

Abstract

De plus en plus utilisée dans les annonces publicitaires, la rhétorique se présente comme l'ultime moyen pour augmenter la visibilité et l'attractivité de l'annonce publicitaire afin de la rendre plus mémorisable. L'objectif du présent travail est de comprendre et tester l'effet de la publicité rhétorique sur le processus de l'imagerie mentale du récepteur. Des expérimentations ont été réalisées auprès un échantillon de 360 étudiants tunisiens. Les conditions de l'expérimentation ont été contrôlées en fonction de la présence *versus* absence de la rhétorique dans les affiches publicitaires. La phase de création des affiches a donné lieu à trois publicités rhétoriques et à trois autres non rhétoriques. Pour tester l'interaction qui puisse exister entre la rhétorique publicitaire et l'imagerie mentale, une analyse discriminante a été réalisée. Les résultats ont permis de mettre en avant un effet significatif de la rhétorique publicitaire sur le processus de l'imagerie mentale. Face à une publicité rhétorique, le récepteur développe un processus d'imagerie très élaborée ; en revanche, le processus d'imagerie diminue manifestement lorsque l'on traite d'une publicité non rhétorique.

Keywords: Rhétorique, imagerie mentale, analyse discriminante.

Introduction

La surenchère publicitaire à laquelle nous assistons au quotidien oblige les spécialistes publicitaires à se pencher vers des formes d'expression quelque peu conventionnelles. La rhétorique se présente à ce niveau comme la solution créative idéale pour augmenter la puissance à la fois argumentative et attractive des communications publicitaires. L'émergence de la rhétorique est pourtant bien ancienne. Depuis l'époque des sophistes, elle s'impose comme une pratique langagière que l'on craint autant que la force des armes. C'est grâce à Platon alors que les notions de la rhétorique se formalisent et s'installent au cœur de la persuasion. Aujourd'hui encore, la rhétorique est derrière chacune de nos expressions courantes et accompagne les discours usuels que nous proclamons. Utilisée de façon délibérée ou inconscience, la rhétorique nous dote d'une capacité à communiquer efficacement avec autrui. En marketing, la rhétorique acquiert toute son utilité. Elle entretient d'ailleurs des liens étroits avec la publicité si bien que de nombreux chercheurs la considèrent comme une issue automatique pour la construction de n'importe quel type de publicité (LeRoux, 2000 ; Brochand et Lendrevic, 1993). La publicité, dont l'un des objectifs est de convaincre le consommateur du produit ou de l'idée qu'elle présente, trouve dans la rhétorique les recettes de persuasion dont elle a besoin : mises en évidence, hyperbole, redondance, jeux de mots, métaphores, etc. (Leigh, 1994). Force est de constater également que la rhétorique s'inscrit comme une description absurde de la réalité en mesure d'augmenter l'attention du récepteur face à l'annonce (Arens, in Arias et al., 2000) et de l'impliquer davantage dans la lecture de ce qui est derrière la publicité (McQuarrie et Mick, 1999). Pourtant, la publicité rhétorique ne convient pas à tous les goûts et provoque souvent le véhémentement des puristes contemporains à l'encontre des mass-media et de leur langage.

Le succès de la publicité rhétorique dépend, en grande partie, du processus de lecture qui l'accompagne. Ce dernier peut être cognitif ou émotionnel. Herman et Lurgin (2001) rappelle à ce titre que le principal objectif de la publicité rhétorique est de séduire et convaincre le consommateur en empruntant, à la fois, la raison (logos) et/ou l'affect (ethos). Si le processus de lecture émotionnelle implique les émotions du lecteur en tant que base pour les évaluations du stimulus rhétorique, le processus cognitif fait intervenir une variable médiatrice relative au processus de l'imagerie mentale (McQuarrie et Mick, 1999). Les travaux antérieurs mettent en avant le lien étroit

existant entre la publicité verbale et visuelle et l'imagerie mentale (Babin et Burns, 1997; Bone et Allen, 1992; Fennis et al., 2012).

A travers le présent travail, nous ambitionnons à identifier de plus près l'impact des figures rhétoriques contenues dans une annonce publicitaire sur le processus de l'imagerie mentale du récepteur. Pour cela, une analyse discriminante est opérée en vue de comparer, statistiquement, l'effet de deux affiches (avec et sans rhétorique) sur le processus de l'imagerie mentale.

Revue De La Littérature

Rhétorique et publicité

Lors de la conception de leurs messages, les publicitaires sont supposés respecter certaines exigences liées principalement à la manière avec laquelle le récepteur reçoit, perçoit et interprète le message : concision, choix des mots et du ton. Selon Durand (1970), la figure rhétorique est «*une proposition qui, partant d'une opération simple, modifie certains éléments de cette proposition.* » (p70).

Les figures rhétoriques peuvent être regroupées, selon Brouland (2006) en trois catégories : figures de mots, figures de construction et figures de pensées (Schéma1). Les figures de mots servent à donner un nouveau sens aux mots, parfois en se basant sur la sonorité des mots. Les figures de style les plus utilisées sont la métaphore, la métonymie, l'oxymore, la synecdoque, etc. (Barbu-Kleitsch, 2015). La figure la plus utilisée par rapport à la sonorité des mots la paronomase et qui consiste à utiliser des mots voisins dans une même expression, généralement un slogan. Les figures de construction modifient, grammaticalement parlant, les mots en inversant l'ordre. Quant aux figures de pensée, les publicitaires utilisent généralement l'hyperbole, le détournement de citations connues ou d'expressions familières, etc. (Brouland, 2006).

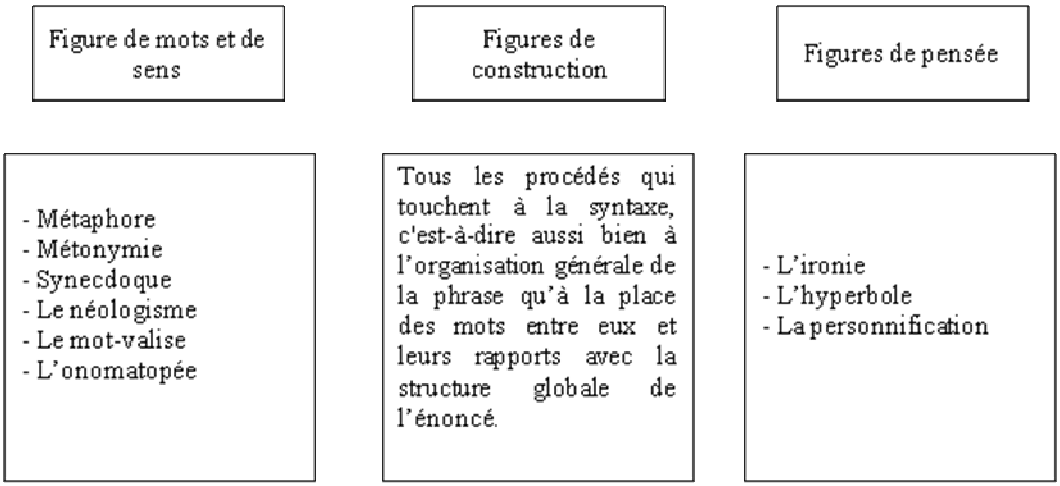

Schéma 1 : Les figures rhétoriques selon Brouland (2006)

Les publicitaires expriment une appétence toute particulière pour les figures rhétoriques vu qu'elles permettent d'améliorer le rappel et de produire une attitude plus positive envers l'annonce. LeRoux (2000) avance dans ce sens que pour éveiller le consommateur d'aujourd'hui, un consommateur lassé par la suprématie publicitaire, l'annonceur « *peut utiliser le placere (i.e. plaire) par des jeux de mots et des figures de styles et/ou le docere (i.e. enseigner) en frappant les esprits par des exemples et des arguments* ». Il fait d'ailleurs ressembler le publicitaire à l'orateur classique qui doit attirer l'attention de la foule assemblée et capter son attention compte tenu de toutes les variables individuelles et contextuelles environnant cet échange communicationnel. La rhétorique pourrait même être utilisée par l'entreprise pour susciter un bouche-à-oreille de la part du consommateur (Fox et Rinaldo, 2014).

Or pour qu'elle acquière toute son importance, la publicité rhétorique, doit conduire à des effets persuasifs chez le lecteur. Chez McQuarrie et Mick (1996), la persuasion publicitaire des annonces rhétoriques passe par le processus de l'imagerie mentale que nous étayons dans ce qui suit.

Rhétorique publicitaire et imagerie mentale : quel rapport ?

Le concept de l'imagerie mentale qui est longtemps resté cloîtré aux domaines philosophique, psychologique et médical, est aujourd'hui intégré au marketing, et plus précisément à la communication persuasive (Chamard, 2000). Par imagerie mentale, on entend toute sorte de traitement visuel de l'information. Appliqué à une annonce publicitaire, ce dernier est à même de rendre compte d'une évaluation globale ou holistique de l'annonce (contrairement au traitement analytique détaillé des éléments de l'annonce) (Euzeby, 2001). Les individus qui s'engagent dans un processus de l'imagerie mentale partent du stimulus (qui est ici l'annonce rhétorique) et créent des représentations mentales imagées (MacInnins et Price, 1987, 1990 ; Ellen et Bone, 1991 ; Babin *et al*., 1992 ; Helme-Guizon, 1998).

L'approche cognitive, basée sur le processus de traitement de l'information, est jugée « *plus pertinente pour la compréhension de l'impact du contenu de l'annonce, sur les réponses cognitives et affectives* » (Helme-Guizon, 1998). En effet, compte tenu de la nature du stimulus (une image rhétorique ou un slogan figuré) et conformément aux études antérieures (MacInnis et Price, 1987 ; Babin et al., 1992 ; Helme-Guizon, 1998 ; Euzeby, 2001), l'imagerie mentale est un concept de base qui est mieux capable d'appréhender le rôle de la rhétorique publicitaire. Ce choix est justifié par (1) le fait que la publicité rhétorique renferme plus d'une stratégie de l'imagerie mentale (stimulus iconique, incitations directes à imaginer, etc.) et (2) le fait que l'inclusion d'une forme rhétorique (au niveau de l'image ou du texte) dans une annonce publicitaire augmente considérablement le travail d'élaboration chez la personne exposée (McQuarrie et Phillips, 2005). En d'autres termes, « *il est possible de démontrer d'une manière expérimentale que l'annonce qui contient des figures rhétoriques (visuelle notamment) produit un plus grand degré d'élaboration relativement à une annonce qui n'en contient pas* » (McQuarrie et Mick, 1999).

Les différents travaux de la littérature consentis autour du concept de l'imagerie mentale reconnaissent que cette dernière est souvent provoquée par un stimulus bien déterminé. Seulement, aucun de ces travaux n'a validé la relation exclusive qui pourrait exister entre la rhétorique de la publicité et l'imagerie mentale. Pour le cas particulier de la publicité rhétorique, McQuarrie et Mick (1999) affirment que les figures de style incluses dans une publicité augmentent considérablement le niveau de l'élaboration à travers le déclenchement d'un processus d'imagerie mentale.

Par ailleurs, d'après la définition de Miller (*in* Chamard, 2000), toute technique de stimulation de l'imagerie mentale utilisée lors du traitement d'un message publicitaire peut être considérée comme une stratégie de l'imagerie mentale. Or, la publicité rhétorique renferme des images et des textes en mesure de provoquer des images mentales. De ce fait, elle peut être considérée comme une stratégie d'imagerie mentale. La publicité rhétorique suscite chez le consommateur un processus d'élaboration (McQuarrie et Mick, 1999). Ce dernier peut être verbal et/ou visuel. Le processus d'élaboration verbal correspond au discours que nous proclamons face au stimulus (les contre arguments, les attributions, les approbations…), alors que le processus d'élaboration visuel correspond au processus de l'imagerie mentale que nous développons (rêveries, fantaisies, fantasmes, résolution visuelle de certains problèmes…) (MacInnis et Price, 1987). Par conséquent, la publicité rhétorique est à même de générer un processus d'élaboration qui peut aller du mode verbal au mode visuel (ou imagerie mentale).

Il serait, de ce fait, pertinent de tester la relation entre la publicité rhétorique et le processus d'imagerie mentale et cerner les différences qui puissent exister entre l'imagerie mentale dans les deux contextes publicitaires rhétoriques et non rhétoriques.

Méthodologie Adoptée

Echantillon

Dans une première étape du processus d'échantillonnage, nous avons procédé au choix de notre population mère : les étudiants en Tunisie. A une seconde étape, nous avons opté pour une méthode d'échantillonnage non probabiliste, notamment la méthode par convenance. Toutefois, l'échantillon n'a pas été restreint à un seul niveau d'études, ni à une seule spécialité. Nous avons, en effet, veillé à diversifier et les niveaux d'études et les spécialités afin d'assurer une meilleure représentativité de la population mère. Aussi, notre échantillon est-il composé de classes du marketing, du management, des études comptables, de la finance et de l'actuariat et assurances. Les niveaux d'études étaient à leur tour variés : des classes de la deuxième, de la troisième et de la quatrième année ainsi que des classes de mastères, de l'ISG et la FSEG de Tunis et de l'ESC de Sfax. L'échantillon interrogé est composé de 360 étudiants.

Choix des stimuli

Pour tester l'effet des publicités rhétoriques *versus* non rhétoriques sur l'imagerie mentale, nous avons d'abord commencé par choisir les stimuli, à savoir les annonces publicitaires. Afin de garantir la qualité de nos annonces, nous avons fait appel à des publicités professionnelles divulguées sur Internet et dans des magazines étrangers. Le but de choisir des publicités qui ne sont pas locales revient à éliminer tout souvenir ou toute expérience vécue qui s'y rapporte, et donc à minimiser les biais au niveau des mesures. Notons, par ailleurs, que la figure de style contenue au niveau de l'annonce est d'une importance cruciale pour notre recherche. En effet, l'affiche doit non seulement être rhétorique, mais encore faut-il que cette forme de rhétorique soit saillante (McQuarrie et Mick, 1999, 2003) et puisse produire de l'imagerie mentale (Chamard, 2000). Il est à rappeler à ce titre que la rhétorique s'exprime sous plusieurs formes (verbale, visuelle, électronique, chiffrée, etc.). Pour le cas de notre stimulus, nous avons opté pour une forme de rhétorique visuelle vu qu'elle a beaucoup plus d'effet que celle des mots (McQuarrie et Mick, 1999) et que les photos sont par définition des générateurs d'imagerie mentale (Rossiter et Percy, 1978). En somme, les annonces publicitaires ont été choisies selon trois critères principaux : (1) la crédibilité de leur exécution, (2) leur contenance en une forme de rhétorique et (3) leur aspect inconnu.

Le choix de la catégorie de produit est très déterminant. En effet, la personne doit être familiarisée avec le produit pour être capable de former des images mentales à son propos (MacInnis et Price, 1987 ; Rossiter et Percy, 1978). Les catégories de produits sélectionnés en vue d'assurer la familiarité entre le produit, sujet de l'annonce, et les étudiants, échantillon de l'enquête sont (1) le déodorant pour homme pour la cible masculine, (2) le salon de coiffure pour la cible féminine et (3) le gel coiffant pour les cibles féminine et masculine. Les affiches sélectionnées ont toutes été sujettes à des réarrangements. Pour y parvenir, nous avons fait appel à deux professionnels en infographie qui se sont chargés tour à tour des manipulations des annonces. Ce travail s'est fait d'une manière séquentielle et chaque affiche est passée par des manipulations de la part de chacun des infographistes. Le but d'un tel exercice était de garantir une meilleure qualité d'exécution. Les réarrangements en question ont touché le nom de marque (création d'un nom de marque fictif), le slogan (traduction des slogans des publicités non françaises et l'adapter, dans certains cas, au contexte tunisien) et le produit. L'étape de sélection des annonces publicitaires a également fait l'objet de vérification de la part deux juges chargés de la lecture des annonces pour vérifier si elles contiennent bel et bien des figures rhétoriques, s'assurer du degré de force de ces figures, identifier la ou les figure(s) spécifique(s) à chaque annonce et arriver à une lecture plus détaillée des annonces (démarche détaillée à l'annexe 1).

Choix de la mesure de l'imagerie mentale

L'échelle de l'imagerie mentale développée par Ellen et Bone (1991) marque un point de départ vers une mesure « *systématique* » du concept de l'imagerie mentale (Euzeby, 2001). Cette échelle de mesure de l'imagerie mentale est en effet formée de 6 variables :

(1) la quantité d'images et
(2) l'élaboration

Ces deux variables sont mesurées par des protocoles verbaux.

(3) la facilité de formation des images mentales mesurées par deux items :
   - Images visuelles formées immédiatement / au bout d'un certain temps
   - Images visuelles formées facilement / difficilement
(4) la vivacité mesurée par un item : Images visuelles formées fortes / faibles
(5) la valence mesurée par un item : Images visuelles formées agréables / désagréables

Ces trois dernières variables sont mesurées via des échelles sémantiques différentielles à 5 points (Annexe 2).

RESULTATS

Une fois la collecte terminée, les données codées et saisies, nous avons procédé à une analyse en Composantes Principales via le logiciel d'analyse de données quantitatives SPSS 18.0. L'échelle de l'imagerie mentale est bidimensionnelle (Annexe 2). Les deux axes qui la décrivent se présentent comme suit :

Axe 1- La facilité de l'imagerie mentale

Axe 2- Les traits des images mentales

Pour explorer le lien entre la présence *versus* l'absence de rhétorique dans l'annonce publicitaire sur l'imagerie mentale, une analyse discriminante a été réalisée. L'objectif principal de cette analyse est d'étudier les relations entre une variable qualitative (présente ou absence de rhétorique) sur une ou plusieurs variables quantitatives (les deux dimensions de l'imagerie mentale) (Fisher, 1936).

Nous apprécions l'interaction entre l'existence de la rhétorique et le développement de l'imagerie mentale à travers un axe factoriel discriminant issu d'une analyse discriminante. Nous cherchons, à cet effet, à discriminer entre les deux types d'affiches (avec ou sans rhétorique) selon les deux dimensions de l'imagerie mentale, découlant des résultats de l'ACP, à savoir la sensibilité aux images mentales et la facilité de l'imagerie. Au niveau de sa construction, cet axe discriminant traduit la part de l'imagerie mentale qui est exclusivement déclenchée suite à l'existence de la rhétorique. En effet, comme on peut voir sur la figure suivante, l'axe discriminant est entrain d'associer une part importante de l'imagerie mentale développée par les personnes exposées à l'annonce à la présence de la rhétorique.

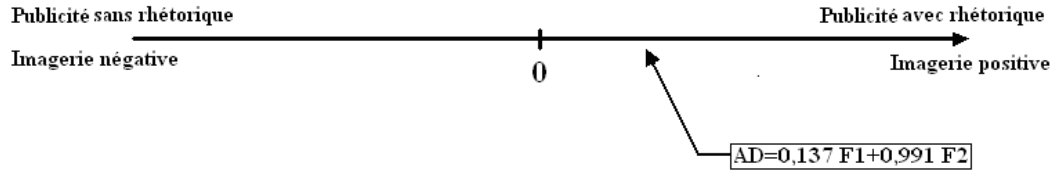

Figure 2 : Présentation schématique de l'axe discriminant

Sur le plan statistique, les résultats de l'analyse discriminante sont apparus très significatifs. Ces résultats se présentent comme suit :

Tableau 1 : Analyse discriminante : *Wilks' Lambda*

Test of Fonction(s)	Wilks' Lambda	Chi-square	df	Sig.
1	0,975	8,161	2	0,017

En effet, comme on peut le constater sur le tableau qui précède, que l'axe retenu montre que la capacité de développer de l'imagerie mentale est d'autant plus élevée lorsqu'il est associé à une publicité rhétorique. Le test de Chi-deux est sans ambiguïté, puisque le niveau de significativité, de 0,017, nous emmène à rejeter l'hypothèse H_0 selon laquelle les deux dimensions de l'imagerie mentale ne permettent pas de discriminer entre les deux types de publicités.

La position des deux types de publicités sur cet axe (avec ou sans rhétorique) est indiqué par le tableau 2 : la publicité avec (respectivement sans) rhétorique associe une valeur positive (respectivement négative) et occupe, par conséquent, le côté droit (respectivement gauche) de l'axe. Parallèlement, ce dernier apparaît comme positivement corrélé avec la sensibilité aux images mentales et la facilité de l'imagerie mentale.

Tableau 2: Analyse discriminante: *Functions at Group Centroids*

Rhétorique	Fonction
Avec	0,187
Sans	-0,135

Toutefois, le tableau 3 montre que seule la dimension de la sensibilité aux images mentales se présente avec un effet discriminant significatif.

Tableau 3 : Analyse discriminante: Test d'égalité des moyennes

	Wilks' Lambda	F	df1	Sig.
Axe 1 (F1)	1	0,149	1	0,700
Axe 2 (F2)	0,976	8,133	1	0,005

De fait, au niveau de la première ligne du tableau 3, nous tentons de faire le test suivant :

H_0 : La facilité de l'imagerie mentale ne permet pas de discriminer entre les deux types de publicités.
H_1 : La facilité de l'imagerie mentale permet de discriminer entre les deux types de publicités.
Ce test est significatif (sig.= 0,7) et l'hypothèse **H_0** n'est pas rejetée ; c'est-à-dire que la facilité de l'imagerie mentale ne permet pas de discriminer entre les deux types de publicités.

En revanche, la deuxième ligne de ce même tableau permet le test suivant :
H_0 : La sensibilité aux images mentales ne permet pas de discriminer entre les deux types de publicités.

H_1 : La sensibilité aux images mentales permet de discriminer entre les deux types de publicités.
Ce test n'est pas significatif (sig.= 0,005) et l'hypothèse **H_0** est rejetée ; c'est-à-dire que la sensibilité aux images mentales permet de discriminer entre les deux types de publicités, rhétoriques et non rhétoriques. En d'autres termes, seul l'axe de la sensibilité aux images mentales peut discriminer entre les publicités rhétoriques et non rhétoriques.

Conclusion

L'analyse discriminante nous a donné les moyens de construire une nouvelle variable[1] qui rend compte de l'interaction entre la sensibilité aux images mentales et l'existence d'une figure rhétorique au niveau de l'annonce publicitaire. Ceci nous permet dès lors de conclure que l'imagerie mentale augmente systématiquement lorsque l'on traite d'une publicité rhétorique. En d'autres termes, les individus exposés à une annonce rhétorique développent un processus de l'imagerie mentale plus poussé que les personnes qui sont exposées à des publicités contrôlées (sans effet de rhétorique). Face à une publicité rhétorique, l'individu développe un processus d'imagerie très élaborée ; en revanche, le processus d'imagerie diminue manifestement lorsque l'on traite d'une publicité non rhétorique.

En somme, il convient d'avancer que l'imagerie mentale a un effet combiné entre la publicité rhétorique et les réponses à l'annonce. Ceci était rendu possible grâce à une analyse discriminante qui montre l'interaction entre la publicité rhétorique et l'imagerie mentale et qui est à même de produire une communication plus efficace. Un tel résultat vient soutenir des travaux similaires (Helme-Guizon, 1998 ; Lee, 2006 ; Chamard, 2000 ; Babin *et al.*, 1997) et infirmer les résultats d'autres (McQuarrie et Mick, 1999).

Les publicitaires devraient, de ce fait, reconsidérer l'utilisation de la rhétorique, principalement les caractéristiques des figures de style appliquées et les moyens de les exploiter en vue de produire une imagerie mentale plutôt positive. Par ailleurs seule la sensibilité aux images mentales (deuxième dimension de l'imagerie mentale) peut discriminer entre les publicités rhétoriques et non rhétoriques. La facilité de l'imagerie mentale (première dimension) devrait dépendre d'autres variables, autres que la rhétorique, et qui pourraient être explorées dans de futures recherches.

En revanche, le présent travail présente la principale limite de se focaliser sur l'imagerie mentale en tant que résultante de la présence ou de l'absence de la rhétorique dans un message publicitaire mais ne met pas l'accent sur l'imagerie mentale en tant que variable explicative des futures réactions des consommateurs, principalement leurs jugements attitudinaux (Euzeby, 2001 ; Lao, 2013 ; Yoo et Kim, 2014), leurs réponses envers l'annonce (attitude envers l'annonce et attitude envers la marque) ou alors leurs intentions d'achat (MacInnis et Price, 1987 ; Bone et Ellen, 1990). L'interaction entre la présence *versus* absence de rhétorique dans l'annonce publicitaire est une étape préliminaire avant de passer à l'examen de l'effet persuasif des messages rhétoriques. Il serait possible, dans de futures recherches, de considérer l'imagerie mentale comme une variable médiatrice entre la rhétorique et l'attitude envers l'annonce, la marque ou l'intention d'achat. Il serait également pertinent d'intégrer des variables individuelles comme variables modératrices telle que l'aptitude à traiter l'annonce qui pourrait déterminer le rapport entre la rhétorique publicitaire comme stimulus et le processus de l'imagerie mentale. D'autres variables culturelles peuvent également être considérées comme modératrices.

Annexe 1 : Lecture des annonces rhétoriques et non rhétoriques

La lecture des annonces non contrôlées

Nous avons, en effet, demandé à deux spécialistes en linguistique française de faire une lecture détaillée des éléments des annonces non contrôlées. Chacun des deux juges a transcrit sa propre lecture des trois annonces en question, tout en retraçant les différentes figures de style qu'elles contiennent. Les différences d'identification de la figure appropriée ont été résolues à travers les discussions qui se sont déroulées par la suite entre les deux juges. Les retranscriptions des lectures de ces derniers sont fidèlement reprises dans la partie qui suit.

Les résultats de ces lectures sont présentés dans ce qui suit.

Lecture des trois annonces rhétoriques

Affiches	Lecture de l'annonce	Types de procédés de style
Affiche n°1 : Le déodorant Sure	Cette affiche nous frappe par le nombre considérable de fiches d'électricité femelles qui contournent une seule fiche mâle. La fiche mâle symbolise l'utilisateur du déodorant et les fiches femelles opposées les femmes qui l'entourent. Il s'agit donc d'une **allégorie.** La fiche mâle personnifie le sexe masculin et les fiches femelles le sexe féminin pour donner à l'image un caractère sensuel. Il s'agit là d'une figure rhétorique qui sert comme argument pour inciter le récepteur à utiliser le produit en question. Cette expression par allégorie donne à l'image un caractère dynamique et par les charges négatives et par les charges positives. Ces charges galvaniques connotent ainsi une pulsion très vive. Remarquons, par ailleurs, l'existence d'un **paradoxe** (entre les fiches mâles et femelles) qui déclenche, certes, une attraction. Cette opposition du nombre considérables de fiches femelles à une seule fiche mâle cherche à montrer que le produit (déodorant) est d'une efficacité singulière : plus on l'utilise, plus on a du succès ! Aussi, un **parallélisme** se crée-t-il entre l'utilisation du produit et le succès social. Le but de ce parallélisme est de mettre en relation les différents éléments argumentatifs : le produit se présente comme le moyen idéal pour maintenir l'équilibre, le succès et l'harmonie avec l'entourage social.	- Allégorie - Paradoxe - Parallélisme

Affiche n°2 : Le gel coiffant Style	Quoi qu'elle soit plate et simple en apparence, cette annonce peut être sujette à plusieurs interprétations. Le noir des cheveux, le vert des pupilles dans une surface blanche rejoint l'éclat des dents dessinant un sourire, signe de satisfaction. Le visage du jeune homme comme l'ocre rassemble ses éléments expressifs pour donner à l'image un caractère vraisemblable. On remarque des couleurs plates exprimant la limpidité, la clarté et la simplicité, dans une sphère absolue. Cette simplicité est toutefois brisée par une **métaphore** qui donne aux cheveux la forme d'un bras excessivement musclé. L'affiche acquiert ainsi un caractère impressionnant grâce à un photomontage rassemblant la photo du jeune homme, image de monsieur tout le monde, et les cheveux dressés sur la tête sous forme d'un bras fort. A la **comparaison** (cheveux comparés à un bras musclé), s'ajoute une **hyperbole** pour accentuer l'efficacité du gel. Cette hyperbole a un double emploi de l'impression à la persuasion. Plus les cheveux que nous constatons sont si forts, plus le produit est si efficace. Dans ce **parallélisme**, il y a un rapport de **causalité**. Il s'agit d'un va-et-vient entre la cause (le gel coiffant) et l'effet (la force des cheveux) dont le but est de convaincre le consommateur. Cette annonce, par les procédés qu'on vient de déceler, renvoie à une image amplifiée de la force du gel coiffant Style.	- Métaphore - Hyperbole - Parallélisme

Affiche n°3 : Le salon de coiffure pour dames La Bella	Cette affiche prend à l'initiale une position par l'emploi du terme « vos cheveux ». L'adjectif possessif « vos » implique le récepteur et l'emmène progressivement à participer dans le raisonnement de l'annonceur. Le mot « soucis » suscite une problématique réelle pour arriver à une mise en évidence **hyperbolique** d'un état psychologique perturbé. Le verbe « envahir » implique un caractère excessif. Il est responsable de la situation de morbidité. On déduit une relation de **cause-effet** entre le groupe nominal et le groupe verbal. Cette relation est enflée par une image troublante. En effet, on est en présence d'une dame dont le visage ne manque pas de signes de beauté. Sa grâce est en effet manifeste par rapport à l'envahissement des cheveux qui mettent en évidence un **paradoxe** entre l'état d'âme et les traits physiques. Cette beauté certes est abîmée, étouffée par la laideur des cheveux. Le salon de coiffure vient au secours par ses couleurs gaies : jaune, saumon, beige, bleu ciel…et se propose comme moyen pour délibérer cette beauté et entre en dualité avec la laideur. Cette affiche utilise alors cette **dualité** entre le mal et le bien (thème de tous les temps). Les éléments contrastants entre cheveux et visage montrent que le salon de coiffure dispose d'un pourvoir surnaturel et fait appel aux forces extérieures pour sauver la beauté. On cherche ainsi à convaincre le récepteur de l'utilité, de l'importance, de l'efficacité du salon de coiffure dans notre vie quotidienne. Le point d'interrogation mis en œuvre à travers le questionnement du départ et la photo de la dame met le récepteur dans une situation d'intrigue. Celle-ci constitue, alors, la partie attrayante de l'affiche. Les figures utilisées oeuvrent mutuellement à mettre en valeur le salon en question.	- Hyperbole - Paradoxe - Métaphore

Les lectures élaborées par les deux juges nous ont permis de comprendre le message que les affiches rhétoriques tentent de communiquer et de créer d'autres affiches, déclinées des premières et dont le contenu n'est pas rhétorique. La rhétorique publicitaire est une variable qualitative dont la mesure n'est pas fournie. Nous avons tenté alors de procéder à son opérationnalisation via la création de deux sortes d'affiches : une qui contient une forme de rhétorique et une autre qui n'en contient pas.

La création des affiches à contenu non rhétorique

Au niveau de notre recherche, la rhétorique forme une variable de contrôle. Nous avons opté pour la création d'une déclinaison de chacune de nos affiches à contenance rhétorique[2]. En effet, nous sommes partis d'annonces déjà existantes revendiquant les mêmes produits que nous avons choisis. Des transformations ont été opérées par la même équipe d'infographistes. Elles ont touché aux points suivants :

* Coller le même nom de marque à l'annonce contrôlée

* Orienter le texte du base line et de l'accroche vers un sens très explicite en accord avec l'affiche rhétorique équivalente

[2] Cette méthode a été adoptée par de nombreux chercheurs (exemples : McQuarrie et Mick, 1999 ; Chakraborty et Mowen, 2000)

* Transformation au niveau du visuel pour garantir une image à cent pour cent plate (sans rhétorique).

Les versions finales des annonces contrôlées et non contrôlées ont été produites sous un format professionnel en couleurs, suite à quoi nous avons procédé à nos mesures. Rappelons, par ailleurs, que la rhétorique est une variable qualitative qui a été contrôlée par la création de deux types d'affiches, une avec rhétorique et une autre sans rhétorique, afin d'arriver à la mesurer.

Annexe 2 : Echelle de mesure de l'imagerie mentale utilisée et analyse en composante principale réalisée

Images visuelles formées immédiatement	1-----2-----3-----4-----5	au bout d'un certain temps
Images visuelles formées facilement	1-----2-----3-----4-----5	Images visuelles formées difficilement
Images visuelles formées fortes	1-----2-----3-----4-----5	Images visuelles formées faibles
Images visuelles formées agréables	1-----2-----3-----4-----5	Images visuelles formées désagréables

- **<u>Etape n°1</u> : La vérification de la fiabilité de l'échelle**

Le test de sphéricité de Bartlett et le test de KMO confirmant la validité de l'ACP se présentent comme suit :

Tableau n°15 : Indice KMO et test de Bartlett (Détermination de l'imagerie mentale)

Mesure de précision de l'échantillonnage de Kaiser-Meyer-Olkin.	0,539		
Test de sphéricité de Bartlett	Khi-deux approximé	173.039	
	ddl	6	
	Signification de Bartlett	0.000	

- **<u>Etape n°2</u> : La détermination des facteurs**

	Matrice des composantes		**Matrice des composantes après rotation**	
	1	**2**	**1**	**2**
Item 2.1 : Images visuelles formées immédiatement/au bout d'un certain temps	0.822		0.891	
Item 2.2 : Images visuelles formées facilement/difficilement	0.763		0.864	
Item 2.3 : Images visuelles formées fortes/faibles		0.735		0.835
Item 2.4 : Images visuelles formées agréables/désagréables	0.555	0.563		0.768
Variance totale expliquée	43.112	29.093	39.398	32.808
Valeur propre λ	1.724	1.164	1.576	1.312

- Le nombre de facteurs : Le pourcentage des variances a permis de ressortir deux facteurs dont les indices d'inertie λ sont tous supérieurs à 1. En d'autres termes, l'échelle de l'imagerie mentale utilisée est bi-dimensionnelle (mise à part les items de l'élaboration et de la quantité des images mentales).
- Interprétation des facteurs : La matrice des composantes nous permet de ressortir, suite à la rotation effectuée, les facteurs suivants :

Axe n°1 : La facilité de l'imagerie mentale
Cet axe réunit les items 2.1 et 2.2
Axe n°2 : La sensibilité aux images mentales
Cet axe réunit les items 2.4 et 2.3

- **Etape n°3 : La qualité de représentation**
-

Items	**Extraction**
Item 2.1 : Images visuelles formées immédiatement/au bout d'un certain temps	0.793
Item 2.2 : Images visuelles formées facilement/difficilement	0.771
Item 2.3 : Images visuelles formées fortes/faibles	0.624
Item 2.4 : Images visuelles formées agréables/désagréables	0.699

Assessing Students' Satisfaction with Blog Usage for Learning: Focus on Perceived Enjoyment, Knowledge Sharing Experience, and Technology Acceptance Factors

Princely Ifinedo, Cape Breton University, Sydney, Nova Scotia, Canada, princely_ifinedo@cbu.ca

Abstract

This study examines the effects of factors such as perceived enjoyment, knowledge sharing experience, perceived usefulness, and perceived ease of use on students' satisfaction with blog usage for learning in a Management Information Systems (MIS) course. A cross-sectional survey was used to collect data from 108 undergraduate students in a small university in a Canadian Province. Relevant hypotheses on the subject matter were formulated and tested. The partial least squares (PLS) technique was used for data analysis. The results indicate that students' perceived enjoyment, perceived ease of use, and perceived usefulness of blogs have positive effects on students' satisfaction with blog usage for learning MIS. However, the data did not provide support for the positive effect of students' knowledge sharing experience - in the context of blogging - on their satisfaction with the use of such tools for learning MIS. The implications of the study's findings for higher education practitioners and academics are discussed, and suggestions for future research outlined.

Keywords: Knowledge sharing experience, perceived enjoyment, technology acceptance model, blogs, undergraduates

Introduction

A weblog (often shortened to "blog") is a type of website that allows a user (blogger) to publish "posts" which appear in reverse chronological order and are usually archived over a long period of time (Luehmann, 2008). Posts contain frequently updated commentaries, descriptions of events, graphics, photos, videos, and links to other blogs and websites (Lu & Lee, 2012). Blogs use visualization tools to enhance information retrieval and knowledge representation (Kim, 2008; Lai & Chen, 2011). To blog, a user needs to use blogging tools or services that are usually provided by a host (e.g., Blog.com, Wordpress.com, and Blogger.com).

Past studies have shown that the use of blogs in higher educational settings offer useful benefits. For example, Williams and Jacobs (2004) asserted that "blogs have the potential, at least, to be a truly transformational technology in that they provide students with a high level of autonomy while simultaneously providing opportunity for greater interaction with peers" (p. 145). Through blogging, students can create a community supportive of social learning environment where students learn from one another and share knowledge with peers (Du & Wagner, 2007; Ellison & Wu, 2008; Shim & Guo, 2009; Halic et al., 2010). Researchers such as Kim (2008) have argued that blogs are better than traditional computer-mediated communication technologies because the former facilitates interactivity, openness, visualization, and decentralization.

Students' learning experience and ability to communicate and express thoughts with instructors and peers are enhanced by course blogs (Maag, 2005; Halic et al., 2010). Blogging for the purposes of learning in higher educational settings increase students' interaction and reflection (Williams & Jacobs, 2004; Lin et al., 2006; Makri & Kynigos, 2007; Du & Wagner, 2007), collaboration (Ellison & Wu, 2008; Shim & Guo, 2009; Jason, 2009; Zhang et al., 2014), and cooperation (Betts & Glogoff, 2004; Lin et al., 2006; Zhang et al., 2014). Indeed, Lin et al. (2006) noted that students who post rarely, but read the entries and comments of peers benefited from received feedback as well. Furthermore, blogs allow discussions to go beyond the physical classroom (Betts & Glogoff, 2004). However, some researchers (e.g., Divitini et al., 2005) did not find evidence to support the view suggesting that blog use for learning enhance productivity with regard to promoting interactivity among students.

As blog usage in the educational sector spread (Williams & Jacobs, 2004; Du & Wagner, 2006; 2007; Ellison & Wu, 2008; Goldman et al. 2008; Zhang et al., 2014), practitioners and academics are beginning to focus attention on how to evaluate the effectiveness of blog-based learning systems (Halic et al., 2010). While several previous research have examined students' participation in blogging (Goldman et al. 2008; Leslie & Murphy, 2008), attitudes towards blogs (Ellison & Wu, 2008; Lin & Shen, 2013), few have investigated factors that increase students' satisfaction with blog usage for learning purposes (Wang et al., 2012b; 2014; Zhang et al., 2014). This study is motivated by this gap in the literature.

The objective of this study is to examine the effects of perceived enjoyment, knowledge sharing experience, and technology acceptance factors on students' satisfaction with blog usage for learning. Prior studies found perceived enjoyment to be positively related students' intention to blog (Wang et al., 2012a). Perceived playfulness, which is akin to perceived enjoyment, was found to be associated with satisfaction in the context of blog learning (Tang et al., 2014). Knowledge sharing experience was shown to be an important antecedent to intention to continuing updating blogs (Lu & Hsiao, 2007). Beliefs about users' experience with blogging positively impacted their satisfaction with learning with blogs (Tang et al., 2014). Several studies of blog usage and related web-based learning systems have demonstrated strong associations between the constructs of technology acceptance factors, i.e., perceived ease of use and perceived usefulness and usage of such tools (Ifinedo, 2007; Tajuddin et al., 2012; Punnoose, 2012; Lai & Chen, 2011).

Following the foregoing discussion, this study research questions are posed as follows. a) What are the effects of students' perceived enjoyment of blogging, knowledge sharing experience, and perceptions of complexity and usefulness of such tools on their satisfaction with usage of blogs for learning? b) Which of the selected factors is more important for improving students' satisfaction with blog use for learning?

Background and Theoretical Underpinnings

In the study of bloggers' intention to continue updating blogs, Lu and Hsiao (2007) drew from Bandura's (1986) social cognitive theory, which posits that psychological factors, among other factors determine user behavior. Lu and Hsiao (2007) used performance accomplishment, which they represented by knowledge sharing experience and information creation ability to explore behavior relating to updating blogs; they found knowledge sharing experience to be a pertinent antecedent factor in their study. Accordingly, the factor of knowledge sharing experience (KNSE) is considered relevant to this study. KNSE in this study describes a student's experience in sharing relevant and valuable information with peers on a blog site.

According to Ryan and Deci (2000), a person can be motivated to engage in an act for the fun of it rather by external prods. In using the construct of perceived enjoyment (PENJ), Wang et al. (2012a) found it to be relevant to the discourse of students' satisfaction with blogs. Likewise, Hsu and Lin (2008) who used PENJ to study blog usage acceptance found it to be enriching. Here, perceived enjoyment refers to ''the extent to which the activity of using a specific system is perceived to be enjoyable in its own right, aside from any performance consequences resulting from system use" (Venkatesh, 2000).

According to technology acceptance model (TAM) (Davis, 1989), the two main determinants of users' acceptance of technologies are perceived ease of use (PEOU) and perceived usefulness (PUSS). The literature shows that PEOU and PUSS have been used in studies of blog usage (Hsu & Lin, 2008; Tajuddin et al., 2012). PUSS refers to "the degree to which a person believes that using a particular system would enhance his or her job performance" (Davis, 1989, p. 320). PEOU refers to "the degree to which a person believes that using a particular system would be free from effort" (Davis, 1989, p. 320).

Tang et al. (2014) used the construct of satisfaction (SATN) from the expectation–confirmation model and continuance use of information systems (IS) model (Bhattacherjee, 2001; Spreng & Olshavsky, 1993) to examine factors influencing blog learning. These theoretical models propose that users obtain expected benefits from an engagement through usage experiences, which has positive influence on their satisfaction (Tang et al., 2014). Deci and Ryan (2000) noted that satisfaction is essential for the well-being and healthy development of individuals; hence, the choice to include satisfaction as the dependent variable in this study. In this paper, satisfaction refers to the fulfillment of a student's needs and expectations from using blogs to meet their learning objectives.

Research Model and Hypotheses

Based on the foregoing discussion, the research model, which is depicted in Figure 1, is proposed. It shows the effects of the four independent factors on satisfaction with blog usage for learning. The formulated hypotheses are discussed next.

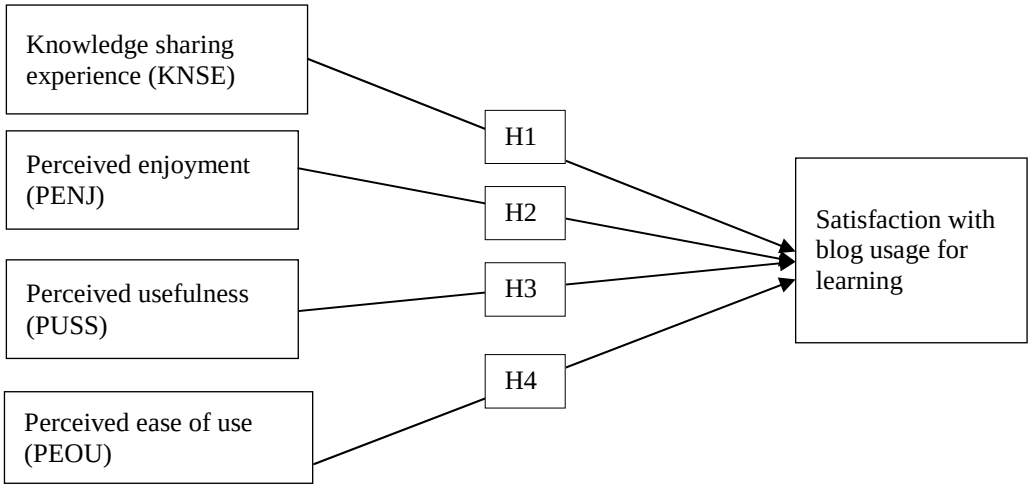

Fig. 1: Research model

The need to collaborate or share knowledge is among the reasons why students use blogging in higher educational settings (Ellison & Wu, 2008; Goldman et al. 2008; Betts & Glogoff, 2004; Lin et al., 2006; Zhang et al., 2014). Studies found that motivation to share knowledge is in fact a key determinant for participant's intention to continue to use blogs (Hsu & Lin, 2008). Others have also reported that students' ability to share knowledge with peers lead to enhanced learning outcomes and satisfaction (Jason, 2009; Ellison & Wu, 2008; Halic et al., 2010; Wang et al., 2014). Lu and Hsiao (2007) who used the construct of KNSE found it to be positively related to intention to continue updating blogs. It is expected that students with knowledge sharing experience will be satisfied with using blogging for learning. Therefore, it is predicted that:

H1: Knowledge sharing experience positively affects students' satisfaction with blog usage for learning.

It is been demonstrated that a technology that brings fun and pleasure to a user will intrinsically motivate the individual to adopt it (Koufaris, 2002; Lee, 2010; Wang et al., 2012a). By the same token, feelings of joy and pleasure matter in explaining user acceptance and usage behavior of web-based learning systems (Saadé et al., 2008). Lee (2012) and Punnoose (2012) who used PENJ to investigate students' motivation to use web-based learning tools found it to be a strong intrinsic motivator. Researchers such as Hsu and Lin (2008) and Lee (2010) revealed that PENJ is an important antecedent to blog usage. Similarly, Wang et al. (2012a) reported that PENJ significantly

influence blogging intention. Thus, it is expected that students who enjoy using blogs to learn will be satisfied with its use in learning environments. Therefore, it is predicted that:

H2: Perceived enjoyment positively affects students' satisfaction with blog usage for learning.

Several studies have demonstrated that the effectiveness of learning technologies is enhanced when learners appreciate the usefulness of such systems (Ferris, 2003; Chang & Wang, 2008). PUSS has a significant effect on user satisfaction in the mandatory technology adoption setting (Adamson & Shine, 2003; Tang et al., 2014). User learning satisfaction benefits from users' perceptions of the usefulness of adopted systems (Chang & Wang, 2008; Lee & Lee, 2008; Sørebø et al., 2009). Also, studies of blog usage have shown that PUSS is positively associated with the users' satisfaction with such technologies (Tang et al., 2014). Therefore, it is predicted that:

H3: Perceived usefulness positively affects students' satisfaction with blog usage for learning.

In general, PEOU relates to ease of access and navigation of technologies (Park, 2009; Agudo-Peregrina et al., 2014). Prior research has shown that technologies used in learning environments are readily accepted when users perceive such to be less complex or easy to use (Ifinedo, 2006; 2007; Chang & Wang, 2008; Lin, 2011; Merhi, 2015). Luehmann (2008) implied that the ease of use of blogs by teachers determined the extent to which they derive benefits from the technology. In fact, PEOU is among key factors that need to be in place in order to enhance bloggers' intentions to continue sharing knowledge through blogs (Hsu & Lin, 2008; Tajuddin et al., 2012).

H4: Perceived ease of use positively affects students' satisfaction with blog usage for learning.

Research Method

Background

A survey research design was used to investigate students' perceptions of and experiences with blog use in an undergraduate class of Management Information Systems (MIS) at a small university (i.e., average class size of 25) in a Canadian province of Nova Scotia. Each student taking the course was asked to create a blog on any concept taken from the course text. Each blog must be unique in its content; similar topics were not allowed to encourage varied blog entries. Students were asked to review the blogs of peers and provide comments/feedback. Students were instructed to respond to all received comments/feedback. Students were also advised to link online resources, i.e., videos and other graphic materials to buttress their points. To motivate students, the instructor informed students that the multiple-choice section of the class tests will include items taken from entries in students' blogs.

The assumption of the blogging task was that "learning occurs by means of reflection and engagement, enabled by the asynchronous nature of the blogs" (Halic et al., 2010, p. 208). The instructor read all the students' blogs. At end of the course, the instructor applied for and received research ethics board approval to survey students' perceptions of blog usage for learning in the MIS class. The questionnaire was self-administered and participation was voluntary. Students were instructed to provide candid opinions on the issues being investigated. Participation was high; the average response rate for the four classes sampled is 94%. The researcher taught the four MIS classes over a period of 18 months. The results of a Chi square test (significant at $p < 0.5$) did not indicate differences in students' opinions on the issues under investigation across the four classes.

Participants

As indicated, the participants in the study were all undergraduate students (n=108), i.e., 51 females and 57 males. They were mainly third and fourth year students. The participants were all Bachelor of

Business Administration (BBA) students. 84% of the participants were aged between 19 and 24 years. 81.5% of them (88) have 8 years and more experience using the Internet. 55.6% (60) were familiar with blogs before taking the course and 44.4% (48) were not. 32.4%, 59.3%, and 8.3% of the students used Blog.com, WordPress.com and other blogging sites, respectively for the assignment.

Instrument

To ensure content validity, the items used to operationalize the study's constructs were obtained from validated sources in the extant literature. Items used to represent knowledge sharing experience were adapted from Lu and Hsiao (2007). The scale items for perceived enjoyment were taken from Lai and Chen (2011) and Lee (2010). Measuring items for the constructs of perceived ease of use and usefulness were adapted from Davis (1989), Lin (2011), and Merhi (2015). Measures used to operationalize the construct of satisfaction with blog usage for learning came from Lee (2010) and Tang et al. (2014). All the questionnaire items used a seven-point Likert-type scale ranging from strongly disagree (1) to strongly agree (7). The Appendix shows the items used in the questionnaire.

Data Analysis

The partial least squares (PLS) technique was used for data analysis. PLS is similar to regression analysis; however, it allows the use of latent constructs (Ifinedo et al., 2010; Kock, 2014). PLS was selected for its suitability for hypothesis testing rather than theory confirmation (Hair et al., 2011). PLS is suitable for studies with small sample sizes like this one (Hair et al., 2011). WarpPLS 4.0 software (Kock, 2014) was used to conduct PLS analysis. Information on the measurement and structural models are provided next.

Measurement model

Information provided for the measurement includes internal consistency, convergent validity and discriminant validity. These assessments ensure that the study's measures are psychometrically sound (Ifinedo et al., 2010; Hair et al., 2011). Two tests of internal consistency of measures are composite reliability (COM) and Cronbach's alpha (CRA) values. Values no less than 0.70 are considered adequate for assessing the internal consistency of variables (Fornell & Larcker, 1981). Table 1 shows that CRA and COM are consistently above the threshold value of 0.70.

To assess convergent validity and discriminant validity, Fornell and Larcker (1981) recommended that the average variance extracted (AVE) should be at least 0.50. In addition, the square root of AVE should be larger than the correlations between that construct and all other constructs. Cross-loadings of the study's constructs were assessed as well; the results for this are adequate (excluded due to space consideration, but are available upon request). Table 1 shows the psychometric properties of the study's constructs.

Table 1: Composite reliability, Cronbach Alphas, AVEs, and inter-construct correlations

	COM	CRA	AVE	KNSE	PENJ	PEOU	PUSS	SATN
KNSE	0.834	0.698	0.631	**0.794**	0.225	0.304	0.202	0.25
PENJ	0.972	0.964	0.875	0.225	**0.935**	0.555	0.774	0.815
PEOU	0.913	0.870	0.727	0.304	0.555	**0.853**	0.577	0.593
PUSS	0.964	0.950	0.870	0.202	0.774	0.577	**0.933**	0.784
SATN	0.969	0.959	0.860	0.25	0.815	0.593	0.784	**0.927**

Note:
a) Cronbach's alpha (CRA); composite reliability (COM); average variance extracted (AVE); knowledge sharing experience (KNSE); perceived enjoyment (PENJ); satisfaction (SATN); perceived usefulness (PUSS); perceived ease of use (PEOU);
b) Off-diagonal elements are correlations among constructs;
c) The bold fonts in the leading diagonals are the square root of AVEs.

Structural model

Information provided in structural models includes the regression coefficient, i.e., beta (β) and their path significance, and the R^2 (coefficient of determination). The WarpPLS 4.0 results for the βs and the R^2 are shown in Figure 2. The independent constructs in the model explained 75% of the variation in the dependent variable: SATN.

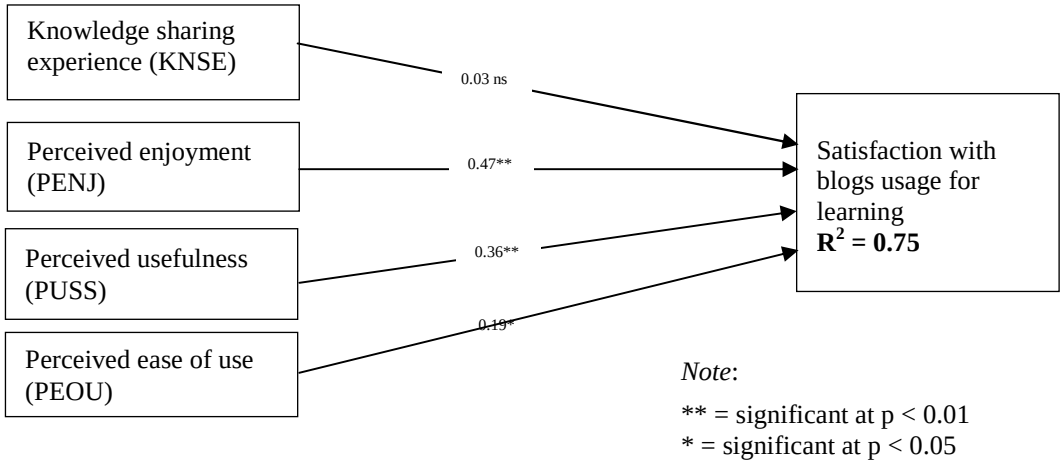

Fig. 2: Results for the proposed model

Three out of the four formulated hypotheses were supported significantly. H1 was unsupported as students' knowledge sharing experience did not have positive effect on their satisfaction with blog usage for learning MIS (β = 0.03, p = 0.37). Students' perceived enjoyment of blogs has a significant positive effect on their satisfaction with using the tool for learning MIS (β = 0.47, p < 0.01) to support H2. The data supported H3, which predicted that students' perceived usefulness of blogs would positively affect their satisfaction with blog usage for learning MIS (β = 0.36, p < 0.01). H4, which predicted a positive association between perceived ease of use of blogs and satisfaction with the tool for learning MIS was also supported by the data (β = 0.19, p < 0.01).

Discussion

Using constructs from relevant theoretical frameworks, this study examined the effects of perceived enjoyment, knowledge sharing experience, and technology acceptance factors on students' satisfaction with blog usage for learning in an MIS course. The proposed model was supported by empirical data, which showed that the selected four independent constructs explained a significant amount of variation in the dependent variable.

The result indicates that students' knowledge sharing experience has no meaningfully relationship with their satisfaction with using blogs to learn in the MIS class. This finding is inconsistent with the body of knowledge indicating that students' experience and ability to share knowledge on blogs positively impacted their learning outcomes and satisfaction (Lu & Hsiao, 2007; Ellison & Wu, 2008; Halic et al., 2010; Wang et al., 2014; Zhang et al., 2014). A plausible explanation for the lack of

support for this hypothesis might be related to the fact that students in the course were asked if they had experience with sharing interesting and valuable information on MIS concepts and topics. Given that MIS is novel to them, responses received might be reflecting their inability to comfortably share useful and relevant information on MIS concepts with peers. Perceptions may vary for other courses.

Perceived enjoyment in the context of this study's research conceptualization was found to be the *most* important factor that can improve students' satisfaction with blog usage for learning MIS. This result supports the viewpoint indicating that students while having fun with learning technologies do derive contentment and satisfaction from the use of such tools. The result is in agreement with the observations of others in the area (Wang et al., 2012a; Lee, 2010; Punnoose, 2012).

Students' satisfaction with blog usage for learning MIS increased with favorable perceptions of the usefulness of the tool. This result is in line with findings in previous studies, which showed that satisfaction with learning technologies, in general (Ferris, 2003; Lee & Lee, 2008; Sørebø et al., 2009) and blog learning satisfaction, in particular (Tang et al., 2014) are favorably impacted by users' perceptions of the usefulness of such technologies.

Implications for research

Discussions on the applicability and limitations of TAM abound. Given that students in this study were mandated to use (Adamson & Shine, 2003) blogs for the MIS assignment, the putative dependent variables of "usage/use" or "intention to use" employed in TAM studies were not considered. Rather, satisfaction was used instead because it signifies the importance of evaluating students' contentment with the tool, and not just its usage. To that end, by employing SATN, this study has helped to shed light on students' contentment with blog use for learning purposes. Other researchers may be enticed to further explore the applicability of SATN in understanding students' acceptance of blogging tools for learning purposes especially in situations where the use of such tools is mandatory. Employing TAM alone may not permit the emergence of useful insights in this regard.

The proposed research model integrated constructs such as perceived enjoyment with TAM's constructs to contribute to the literature on blog acceptance by university students. The study's research model was simplified for parsimony; other relevant relationships among the constructs could be investigated in future studies. For researchers, this study demonstrates that students' satisfaction with blog usage for learning a course such as MIS is impacted *mostly* by the intrinsic motivation of perceived enjoyment derived from using such tools. Others may investigate potential antecedents to this particular factor.

Implication for practice

To encourage effectiveness of blog use for learning, higher education management and instructors should endeavor to promote measures that encourage knowledge sharing skills among students. In particular, necessary tips and information should be provided to students where prior background knowledge and expertise may be required. When students acquire needed expertise and experience, their satisfaction with the technology will accordingly be enhanced.

Efforts to encourage students deriving fun and pleasurable experiences from blogging should be proactively promoted. For instance, students could be asked to link their blogs to online resources, e.g., videos and other materials (academic and otherwise) that support central ideas in the courses they take at school. Millennials tend to use online resources for pleasurable experiences (Wagner, 2013); learning can explore this opportunity as well. The instructor/researcher noticed that students in the MIS course used online resources, e.g. videos extensively for the assignment. Blogging engagements provide a good opportunity to link online fun resources to learning; this can be rewarding, and should be exploited.

University should encourage their learning centres and departments to continually train both instructors and students on the advantages of blog usage for learning and teaching. Training on how to utilize suitable blogging resources for learning and teaching should be encouraged to diminish anxiety among users. Training can improve perceptions of the usefulness and ease of use of blogging tools for learning purposes in higher education settings. In accordance with the tenets of the expectation–confirmation model, satisfaction with blog usage for learning and teaching ensues when users' understanding of the tool is favorably impacted.

Limitations and future research directions

A convenience sample, which was constrained by extraneous factors in the research location, was used for the study. Admittedly, a random sampling method removes selection bias. Non-response bias cannot be ruled out as the researchers did not compare the views of students who used blogs with those who did not. Common method bias exists in this study as both the independent and dependent variables were collected from a single source. As the research subjects who were undergraduate students came from one location, the findings reported in the study cannot be applied to all contexts, including post graduate students and working professionals.

The study's sample size is small; however, PLS places minimal requirement on sample sizes. In fact, the rule of thumb in the PLS literature suggests that a sample size of 40 - based on this study's research model - would have been adequate for the study (Hair et al., 2011). The sampled students' views of blogging were presented from the viewpoint of a single course: MIS. It is difficult to posit with certainty that the same results would be uncovered for other academic courses and disciplines. The noted limitations of this study suggest that caution must be exercised in generalizing the study's findings to all contexts.

Future research can expand this work by considering the following areas. First, efforts must be made to address the noted limitations in the research project. Second, the study's research model did not include all possible factors and constructs from the theoretical frameworks that guided this project; researchers could incorporate constructs such as attitude, confirmation, and intention to further enhance insight. Third, data should be collected from other settings (e.g., larger universities and other countries) to improve the generalizability of the results.

Conclusion

By using relevant constructs, this study aimed to educate on factors that positively affect satisfaction with blog usage for learning in higher learning environments. In this study, students' perceptions of enjoyment, ease of use, and usefulness of blogs were found to have significant effects on their satisfaction with blog usage for learning, in this instance MIS. This study adds to the discourse of students' usage of blogs for learning. It is hoped that information provided in the study will offer beneficial information to administrators and academics on how to enhance the effectiveness and satisfaction with blog usage for learning by university students.

Appendix: Constructs and items used in the survey

Satisfaction with blog usage for learning
I am satisfied with blogs as learning tools.
I am satisfied with blogs as tools for creating and sharing knowledge.
I feel satisfied using blogs for my MIS course.
I am happy I used blogs for learning in my MIS class.
I am pleased with the experience of using blogs for my MIS course.
Knowledge sharing experience
I have experience in sharing valuable or interesting information with peers on a blog site.
I can share valuable or interesting information with peers on a blog site.
I have experience in sharing relevant information with peers on a blog site.
Perceived enjoyment
Using blogs to learn MIS is pleasurable
I had fun using blogs to learn MIS concepts and topics.
Using blogs to learn MIS is pleasant.
I found blogs to be interesting for my MIS course.
I found the use of blogs in my MIS course to be enjoyable.
Perceived usefulness
Using blogs for my MIS course improved my learning performance in that subject.
Using blogs for my MIS course increased my learning effectiveness in that subject.
Using blogs helped me learn MIS better.
Using blogs in my MIS course are helpful in preparing for quizzes/tests.
Perceived ease of use
My interaction with blogs to support my learning MIS is very clear.
Learning to use blogs is easy for me.
I found it easy to use blogs for learning concepts in MIS.
Overall, I believe that it is easy to use blogs to support my learning of MIS.

The Direct and Indirect Effect through Trust of Size Asymmetry on Alliance Performance: The Case of French SMEs

Dr Zoubeyda Mahamadou, University of Pau, France, mzoubeyda@gmail.com

Abstract

The purpose of this paper is to explore empirically the effects of size asymmetry between Small and Medium-sized Enterprises (SMEs) and Multinational Corporations (MNCs) on the performance of these companies in an alliance. We analysis the effects of this asymmetry on alliance performance, both direct effects and indirect ones related to trust from the perspective of ten French SMEs operating in the aircraft manufacturing industry. The previous findings suggest a negative relationship between size asymmetry and performance. Our empirical results reveal that size asymmetry between partners have different direct and indirect effects on performance. These effects depend on the specific dimension of performance under consideration. We observe for example that size asymmetry has no negative direct and indirect effects on financial performance and organizational learning of the SME. In addition, we find that there is a direct and significant negative influence of size asymmetry on relational performance.

Keywords: Asymmetry, Strategic alliances, SMEs, MNCs, Trust, Performance

Introduction

Present-day companies operate in a highly complex and dynamic industrial environment. Globalization and the resulting heightened competition explain the need for some companies to turn to strategic alliances as a way of improving their performance. For such companies, strategic alliances involve pooling their tangible and/or intangible resources to achieve their strategic objectives (Lorange and Roos, 1982).

In recent years the rise of strategic alliances has attracted the interest of many researchers in strategic management (Kogut, 1988; Doz, 1988; Nielsen, 2007; etc.). However, it should be noted that most studies focus on strategic alliances between multinational firms. Analyses of strategic alliances between organizations of different sizes, commonly referred to as "asymmetric alliances", whether in developed or developing countries, are still few and far between. One can count for example the works of (Chen et Chen, 2002; Beamish et Jung, 2005; Katila et al, 2008; Nieto and Santamaria, 2010; Diestre and Rajagopalan, 2012; etc.). Most authors showing an interest in asymmetric alliances argue that asymmetries between partners negatively influence the performance of such alliances (Sarkar et al, 2001; Pérez et al, 2012). Similarly, it has been argued that in an alliance where partners are fundamentally different, trust development can be a daunting task which may subsequently affect the results of the relationship (Bucklin and Sengupta, 1993; Doz, 1988). Consequently, the direct and indirect effect of asymmetries on performance is negative. However, several authors take a very different view. For example, Yeheskel et al. (2001) suggest that the dissimilarity in size enables parent organizations to enjoy each other's unique characteristics. In turn, Beamish and Jung (2005), and Dikmen and Cheriet (2014) found a nonsignificant effect of size asymmetry on alliance performance. Finally, there is a certain amount of theoretical controversy surrounding the effects of size asymmetry between partners on alliance results. These contrasting views make the generalization of empirical results more difficult.

The purpose of this contribution is to overcome these controversies by exploring through case studies the direct and indirect (trust) effects of size asymmetry on the alliance performance. Our empirical study covers asymmetric alliances engaged in by ten French SMEs operating in the aircraft manufacturing industry. Only few studies on strategic alliances focus on French SMEs in alliances with large multinational corporations (MNCs), and none of them has examined the effects of size asymmetry on the performance of such alliances. Furthermore, the aircraft industry presents a

number of asymmetric strategic alliances. In our contribution, performance is addressed from the perspective of one of the partners, the SME.

This paper is organized as follows. First we present a literature review on both a direct and trust-mediated relationship between size asymmetry and performance. Next, we describe the method that we adopted. We then present our results and discussion. The results reported here are a set of propositions challenging traditional views on the relationship between size asymmetry and the results of asymmetric alliances. The article concludes by outlining the implications, limitations and areas for future research.

Background

The concept of asymmetric alliances is one of the most controversial in the field of strategic management research. Indeed, there is no single accepted framework in terms of either the definition of asymmetric alliances or their main characteristics. Generally, asymmetric alliances are referred to cooperative arrangements between MNCs and SMEs aimed at pursuing mutual strategic objectives. Thus the asymmetry is based *a priori* on the size differential. This interpretation of asymmetric alliances is relevant (Pérez et al. 2012) because size asymmetry is the source of other differences between partners (i.e: geographical origin of the partners; level of development; experience in cooperation; growth rate; organizational culture; specificity of the assets exchanged; resources and competencies; absorption and learning abilities; innovation capacity).

Extant research in sociology, marketing and inter-organizational theory have long since stressed the fact that dissimilarities between social actors can make pair interactions difficult (Parkhe 1991). Similarity appears to support attraction between parties, which in turn promotes the development of positive attitudes and leads to favorable results. For example, among research which has tried to identify the effects of size asymmetry on the partnership's results, most of them have maintained that differences resulting from size asymmetry negatively affect alliance performance. Indeed, size asymmetry usually results in an imbalance in the management structure (Yan and Gray, 1994). It also results in a lack of a strategic "fit" between parents (strategic and organizational incompatibilities) which may affect both the quality of the relationship and the partners' satisfaction (Geringer and Hebert 1991; Hill and Hellriegel, 1994).

In a transaction cost approach, strategic alliances which are asymmetrical in size appear to involve high governance and coordination costs (Doz 1988). In order to work together effectively, partners generally commit resources to coordinate their internal procedures and policies. Therefore, according to this perspective, the asymmetry in the partners' size has a negative influence on the performance of the alliance (Yeheskel et al, 2001). In addition, it has been noted that size asymmetry may involve a one-way learning process to the advantage of the dominant partner (Inkpen and Beamish, 1997). This increases the likelihood of relationship instability and can lead to the dissolution of the alliance (Park and Ungson, 1997).

Besides the direct effects of size asymmetry on performance, the literature has shown that this dissimilarity can indirectly affect performance through the trust variable. Trust can be conceptualized as a generalized expectation regarding an exchange partner's reliability and integrity (Morgan and Hunt, 1994). Partners who trust each other generate more profits, better serve their customers and are more adaptable (Kumar 1996). According to Bierly III and Gallagher (2007), it seems that size asymmetry negatively affects trust between the partners to the alliance. For these authors, *"The firm will have more confidence in its ability to predict the behaviour of its partner and understand its routinised regimes if they are more similar. In the same way, two firms that are of similar size are more likely to trust each other because there is less threat of the larger firm using its power to take advantage of the smaller partner"* (p.141). Therefore, size similarity leads to a convergence which facilitates mutual understanding and discourages the emergence of competitive trends, strategic conflicts and hidden agendas, all of which are detrimental to the mutual relationship and trust (Doz 1988).

Taking this into account, one may assume an indirect relationship between size asymmetry and performance due to the relational capital between partners.

Research Methodology

Empirical Background and Justification

Our empirical investigation focuses on ten cases in which French SMEs enter into non-equity asymmetric alliances in the aircraft manufacturing industry. These alliances are typically contractual and do not involve the creation of a separate legal entity for the coordination and management of the project. Indeed, in this paper, we can delineate the partnerships essentially into functional contractual alliances (i.e. joint project for technological development, technology transfer relationship, etc.) and commercial contractual alliances namely original equipment manufacturing contract (Chen and Chen, 2002).

The choice of aircraft manufacturing as a research field is justified firstly by the fact that the aircraft manufacturing industry is a high technology sector characterized by a number of alliances between innovative SMEs and large industrial groups. According to the annual report by GIFAS (*Groupement des Industries Françaises Aéronautiques et Spatiales*), in 2013 the R&D expenditure of the aerospace industry represented 14.7% of its total turnover. Secondly, in the aircraft industry, the pace of innovation in SMEs can be considered as fundamental for the big players (aircraft and components manufacturers) given the role that SMEs play in the production and maintenance of their products. Indeed, the components of aircraft manufactured by MNCs are produced by their partners, including numerous contract manufacturing SMEs. Finally, from a theoretical point of view, the choice of SMEs as a study object is justified by the near absence of research analyzing the performance of strategic alliances from the SME's perspective.

Table 1: describes the ten asymmetric alliances studied in this research. They are all long-standing partnerships and are in their operational phase.

Table 1: Asymmetric Alliances Studied

	Numbers of Employees in the SME	**Numbers of Employees in the MNC**	**Purpose of the Asymmetric Alliance**
Case 1	**44**	More than 20000	Joint project for technological development + commercial relationship (original equipment manufacturing contracts).
Case 2	**30**	More than 20000	Commercial relationship (original equipment manufacturing contracts).
Case 3	**35**	More than 20000	Commercial relationship (original equipment manufacturing contracts).
Case 4	**25**	More than 20000	Joint research programs + Commercial relationship (original equipment manufacturing contracts).
Case 5	**86**	More than 20000	Commercial relationship (original equipment manufacturing contracts) + Technology transfer relationship + Joint R&D project.
Case 6	**138**	More than 20000	Commercial relationship (original equipment manufacturing contracts).
Case 7	**130**	More than 20000	Commercial relationship (original equipment manufacturing contracts)
Case 8	**250**	More than 20000	Commercial relationship (original equipment manufacturing contracts) + Joint product development project.

Case 9	**40**	More than 20000	Commercial relationship (manufacturing) + Research project
Case 10	**100**	More than 20000	Commercial relationship (Maintenance + repair)

We consider that the alliance partners are asymmetric in size when one partner is an SME and the other one is an MNC. Size is appraised in terms of number of employees in the company (Pérez et al, 2012). Companies are considered as SMEs when their headcount is between 20 and 250, in accordance with the European Commission definition. MNCs are enterprises with operations in different countries and with a workforce of more than 500.

In this research we adopt a multidimensional approach to performance analysis. Indeed, as our goal is to understand the phenomenon of asymmetric alliances in its entirety, it seems necessary to evaluate performance by simultaneously considering subjective and objective criteria. We therefore integrate three dimensions of performance into our performance analysis framework (relational, financial and organizational learning). Each dimension of performance addressed in this research is defined by means of subjective assessments by the SMEs involved. In this research we do not address the differences in perceptions that may exist between partners. As pointed out by Geringer and Hebert (1991), the collection of perceptions of only one partner may be sufficient to obtain reliable and efficient data.

Data Collection and Processing

The qualitative method of a multiple case study (Yin, 1984) was chosen for this research. This methodological choice was guided by our goal of achieving a more in-depth understanding of asymmetric strategic alliances phenomenon and the factors affecting their performance. This methodological choice is also guided by the fact that we are working on a sensitive subject and focusing on an industry with a significant culture of secrecy. It is very difficult to get answers from questionnaires in this sector. In our opinion, it is easier to get answers from open interviews, as we did.

With this in mind, for each SME in our sample we conducted in-depth semistructured interviews, each lasting about 1 hour to 1 hour and a half. Each respondent is closely involved in the conduct of their company's asymmetric alliances (Director General, CEO, Commercial director, Director of Operations). Each of our interviews resulted in a thematic coding according to items identified in our theoretical model and transcripts (King 1998). Further, the qualitative analysis was manually conducted.
In addition to data derived from our semi-structured interviews, we used secondary data in order to complete our analysis (public data, studies conducted by recognized organizations, and trade press articles). The use of multiple evidence sources helps to develop a case study (Eisenhardt, 1989).

Finally, we performed the relevant organization and reduction of all data collected in order to compare and understand similarities and differences between the ten asymmetric alliances studied, along with their effects on performance.

Results and Discussion

Direct Relationship Between Size Asymmetry and Alliance Performance

Prior research have suggested that the asymmetry of size impacts negatively the performance of asymmetric alliances (Parkhe, 1991; Inkpen and Beamish, 1997; Yeheskel et al, 2001). In this section, we describe the observations that support or contradict this theoretical assertion. First, we observe, considering our results, that the direct effects of size asymmetry on the results of alliances may be assessed in terms of financial performance, organizational learning and relational performance.

Financial performance. In all cases studied (ten out of ten), we observed an increase in turnover and market share for the SME despite the existence of such size asymmetry between partners. This point is illustrated by the following comments from our respondents.

> *"Despite any differences, the relationship generates market share ... "*, Director General of the SME in Case 1;
> *"There has been a significant increase in our sales and market share. For example in 2011 our level of growth was 325%"*, Director General of the SME in Case 2;
> *"There has clearly been an increase in our turnover and market share. Our growth last year stemmed from the fact that we signed new contracts, but it is also related to the fact that our current client is satisfied with what we have provided, and they recommended us"*, Director General of the SME in Case 3;
> *"When we are involved in a technology transfer alliance with X for all airports, there are royalties; and in terms of turnover, it's very significant"*, Commercial Director of the SME in Case 5.

Organizational learning. The majority of SMEs surveyed (9 cases out of 10) observed an increase in their organizational learning, in terms of both development of their knowledge base and transfer of the MNC's managerial competencies to the SME.

Development of their knowledge base: asymmetric alliances have enabled the SMEs to improve their technical and innovation skills (i.e. improvement in manufacturing processes, acquisition of new technological expertise, product development). Similarly, through these alliances, the SMEs showed a development in their experience in management of asymmetric alliances.

> "*We are acquiring knowledge and new technological expertise. We are also learning manufacturing and product development processes, management skills,..."*, Director of Operations of the SME in Case 6.
> "*In these relationships you will learn a lot. It is not necessarily a transfer of knowledge. They encourage us to innovate further. Their needs drive us to think and innovate"*, Director General of the SME in Case 4.

Transfer of MNCs' managerial competencies to SMEs: in their asymmetric alliances, SMEs have benefited from MNCs in terms of orientation and competencies in organizational and management processes. This has enabled them to become more structured by improving and formalizing their internal management processes.

> "*We very quickly modeled our process on theirs …"*, CEO of the SME in Case 9.
> "*We are growing organizationally by working with them. We can copy their organizational models, yes, absolutely"*, Commercial Director of the SME in Case 10.

The data form this research indicate that despite size asymmetry between partners, asymmetric alliances seem to be effective relationships generating positive quantitative results. These positive results are explained by the existence of complementarities between partners' resources and competences. The combination of a small company's resources with those of a larger one's opens up opportunities for synergies (Harrigan, 1988; Parkhe, 1991; Sarkar et al, 2001) that improve both their economic efficiency (increase in turnover and market share) and their strategic private benefits (organizational learning). As highlighted by the respondent in Case 4, "*On one hand, without them we would not have the money and would have to close. It's that simple ... On the other hand, they come to us for our expertise because it is not necessarily their job, their core business ... There is no choice*". Once pooled, these resources and competencies produce important outcomes for both partners.

Ultimately, asymmetry in term of size has no negative effect, either on financial performance or on organizational learning.

This result corroborates the findings of Beamish and Jung (2005), and Dikmen and Cheriet (2014), who point to the absence of a relationship between asymmetry of size and alliance performance. It should however be noted that it is difficult to draw a comparison with previous studies since we used different proxies to define size asymmetry. Furthermore, our results do not confirm the negative link between size asymmetry and organizational learning as identified by Inkpen and Beamish (1997).
We suggest from our observations that,

Proposition 1: the asymmetry of size does not negatevily affect the financial performance of the asymmetric alliance.

Proposition 2: There is a positive relationship between the asymmetry of size and organizational learning.

Relational performance. Our investigation reveals the existence of relational difficulties between the SMEs and MNCs involved in asymmetric alliances (9 cases out of 10). The analysis of Table 2 highlights that the reason for these difficulties is mainly the uneven balance of power between MNCs and SMEs.

Talking about the asymmetric relationships of his SME, the Commercial Director in Case 10 argued that "*... there is a power relationship that is going to be too visible and much more uneven .... We will be much more at their behest ... they are trying to show their full power. Actually, they are not trying, they are showing it."*

Given their size, MNCs tend to establish a relationship of dominance over their smaller and weaker partners. This results in a certain directiveness by the MNCs during the conduct phase. The SMEs then feel exploited and perceive the MNCs' behavior as opportunistic and lacking in respect and trust. All these factors create a sense of frustration among the SMEs and make the relationship more confrontational for them, as reflected by these comments:

"*They call it partnership, but there is no partnership agreement. There are agreements between an ogre who crushes an ant…"*, Director General of the SME in Case 2;

"We are in a master-slave relationship ... the lords are the MNCs and the beggars are the subcontractors; there is a rather condescending relationship", Director General of the SME in Case 7.

Table 2: Effects of Size Asymmetry on Relational Performance

Cases	Consequences of Size Asymmetry	Verbatim Examples
1	Misunderstanding of mutual organizational cultures.	"Communication is difficult with them due to their organization..." Director General of the SME.
2	The uneven balance of power; Lower level of confidence among MNCs and SMEs; Lack of consideration of MNCs relative to the SMEs.	"They renew the contract as many times as they want, all the clauses are for them and are only made to defend their interests," Director General of the SME.
3	Lack of consideration of MNCs relative to the SMEs; Lower level of confidence among MNCs and SMEs.	"MNCs do not trust the small enterprises because they are risky, they are small…" Director General of the SME.
4	No consequences because of: SME's experience in these projects and adaptation of their management processes to those of the MNC.	"We are used to dealing with them ... our relationships with them are our sole activities..." Director General of the SME.
5	Misunderstanding of mutual	"... our responsiveness is different from

	organizational cultures; The uneven balance of power; Lack of consideration of MNCs relative to the SMEs.	theirs ... there can be a lack of understanding ... from the large group to us" Commercial Director. "We wish the relationship is a Win Win relationship, but not a master-slave relationship...", Commercial Director of the SME.
6	Lack of consideration of MNCs relative to the SMEs.	"One of the great difficulties we have with them is to be taken seriously " Operations Director of the SME.
7	The uneven balance of power; Misunderstanding of mutual organizational cultures; Lack of consideration of MNCs relative to the SMEs.	"We are in a master-slave relationship ..." Director General of the SME. "They would like to have a mirror organization of theirs ... They do not realize that if they had a mirror organization, they would not enjoy many benefits with us ..." Director General of the SME
8	The uneven balance of power	"They are clearly in a strong position…because we have competitors..." Director General of the SME.
9	The uneven balance of power; Lack of consideration of MNCs relative to the SMEs.	"MNCs like X behave badly with us ... they loot us more than they help us growing up" CEO of the SME.
10	The uneven balance of power; Lack of consideration of MNCs relative to the SMEs; Misunderstanding of mutual organizational cultures.	"... there is a power relationship that is going to be too visible and much more uneven ...." Commercial Director. "There are difficulties related to our differences ... The MNC's documentary process is time and energy consuming..." Commercial Director.

Additionally, it is clear from our results that size asymmetry often results both in an imbalance in terms of the partners' management structure and in organizational incompatibilities between them that can lead to mutual misunderstandings (Park and Ungson, 1997; Johnson et al, 1996). These consequences in turn negatively affect the quality of the relationship (Doz 1988; Yan and Gray 1994; Geringer and Hebert, 1991; Hill and Hellriegel, 1994). Finally, it can be argued that size asymmetry resulting in organizational culture asymmetry will therefore have the same negative effects on relational performance.

Finally, our results allow us to establish a direct and significant negative relationship between size asymmetry and relational performance. In formal terms,

Proposition 3: There is a negative relationship between size asymmetry and relational performance.

Indirect Relationship Between Asymmetries and Alliance Performance

Literature emphasizes the existence of a negative relationship between size asymmetry and the development of trust between the alliance partners. Responses relative to that assertion are categorized into two distinct groups, the cases that corroborate previous studies and those that do not.

For the first group (5 cases out of 10 with a dual response from Case 9), size asymmetry negatively influences the development of trust between an SME and a multinational involved in an asymmetric alliance. Firstly because of the power relationship established by the multinational relative to the SME. This result corroborates the findings of Bierly III and Gallagher (2007) which sustains that in case of size asymmetry, the larger firm can use its power to take advantage of the smaller partner. Secondly, because of the SME's lack of credibility. Due to its size, less substantial resources and

simpler organization structure, the SME is seen as a risky organization and seems less credible to MNCs. The perception of this lack of credibility negatively affects the development of trust between partners.

For the second group (6 cases out of 10 with a dual response for case 9), size asymmetry has no negative impact, either on trust between partners or on the development of that trust. Indeed, despite relational difficulties arising from size asymmetry, trust in asymmetric alliances can continue to develop. This will happen if, on the one hand, the SME respects its commitments and satisfies the needs of the multinational, and on the other hand if both partners seek to exploit complementarities arising from their different resources and make efforts to understand each other's organization. This result does not support prior research that suppose negative relationship between size asymmetry and trust (Doz, 1988; Bierly III and Gallagher, 2007).

Overall, we do not observe any significant indirect effects of asymmetry in size on the overall performance of asymmetric alliances. Firstly, because this asymmetry affects trust between partners to a lesser extent. The relational performance is therefore indirectly affected only slightly. Secondly, because partners' financial performance and organizational learning remain positive even in the event of a negative relationship between size asymmetry and trust.

Given these results, we propose these relationship,

Proposition 4: There are no significant effects of asymmetry in size on trust between partners.
Proposition 5: There are no significant indirect effects of asymmetry in size on the overall performance of asymmetric alliances.

Conclusion, Implications and Limitations

The main objective of this contribution was to study the effects of size asymmetry between SMEs and MNCs on the performance of their alliances. The findings are a set of propositions which allows to study the direct and indirect effects through trust of asymmetries in terms of size on the performance of asymmetric alliances. Two main results arise from this study. First, size asymmetry can cause relationship problems between partners. However, despite this asymmetry between partners, alliances generate positive results in terms of financial performance and organizational learning due to the complementarity between the resources of the SMEs and the multinationals involved.

This research has several theoretical and managerial implications. From a theoretical perspective, our results indicate the importance of the partners' characteristics and the effects of these characteristics on trust (relational capital) in explaining the performance of an asymmetric alliance. The direct and indirect effects of size asymmetry between partners on alliance results remain largely underexplored from a theoretical viewpoint. In addition, to our knowledge there is no research on asymmetric alliances that analyzes the relationship between size asymmetry and performance by adopting a multidimensional approach to performance. Most prior studies that address this relationship analyze performance in terms of survival (Harrigan, 1988; Kogut, 1988, Beamish and Jung, 2005), longevity (Parkhe, 1991) and effectiveness (Yeheskel et al, 2001). Our results highlight the importance of considering a multidimensional approach to performance in order to obtain a global vision of the consequencces of asymmetric partnerships.

From a managerial perspective, our results may provide SMEs and MNCs involved in asymmetric alliances with certain means to manage and cope with the relational difficulties they face. It is clear from this research that trust is one of the key success factors of asymmetric alliances. It promotes cooperation and reduces the risk of opportunistic behavior and conflict between partners. When partners trust each other, they generate more profit and serve their customers better (Kumar 1996). However, previous research has confirmed the existence of a negative relationship between asymmetry in size and trust building. Our results emphasize that despite this asymmetry between partners, trust can be developed and can continue to grow if the following conditions are respected:

the SME meets the commitments made towards its bigger partner; the partners' aims are to take advantage of complementarities arising from their different resources and competences; and finally the partners understand each others' procedures and mutually adapt their different organizations. SMEs should consider these factors before engaging in asymmetric alliances and should continue to do so during the conduct of these relationships.

While this study makes significant contributions to the literature on asymmetric alliances, its potential limitations should be highlighted. First, we collected our data from only one side of the alliance (the SMEs). The extent to which the perceptions of all partners would have converged is unknown. Next, our sample size is relatively small, as our empirical analysis was limited to ten asymmetric alliances, although they were carefully selected within the aircraft manufacturing industry in France. Thus a generalization of our results to other cases and other industries should not be carried out without due care. In this perspective, future avenues of research could use this model on larger samples in different industries and diverse geographical areas.

« Du Gouvernement d'entreprise a la RSE : Quels Incidents sur le Processus Décisionnel ? Cas de la SA au Maroc »

Asmaa Boukhima

Faculté des Sciences Juridiques, Economiques et Sociales

Ain Sebaa, Casablanca

Maroc

Sntex@hotmail.fr

Abstract

Aujourd'hui, si la plupart admettent la convergence des deux notions gouvernement d'entreprise et RSE, on se pose toujours la question de savoir si la RSE est une question de gouvernance et quel est le rôle exact des administrateurs à l'égard de cette notion ?

Nous avons essayé à travers ce modeste travail de répondre à ces questions à travers l'analyse des incidences des deux notions sur le processus décisionnel.

Résultat de l'analyse : la RSE est une question de gouvernance, c'est-à-dire qu'elle doit être considérée comme une question organisationnelle stratégique qui requiert une surveillance étroite de la part du conseil d'administration.

Partant de là, la tâche des administrateurs ne cesse de devenir plus exigeante. Chacune des deux notions les conduit à plus de vigilance et de responsabilisation.

Mots clés : gouvernement d'entreprise ; RSE ; société anonyme ;conseil d'administration.

Introduction

L'expression gouvernement d'entreprise ou gouvernance d'entreprise est la traduction du terme anglo-saxon de Corporate Governance. C'est une expression à laquelle plusieurs tentatives de définitions ont été données.

Pour Hyafil par exemple, le gouvernement d'entreprise recouvre l'ensemble des dispositions qui permettent de s'assurer : 1) que les objectifs poursuivis par les dirigeants sont légitimes 2) et que les moyens mis en œuvre pour atteindre ces objectifs sont adaptés (Hyafil 1997).

Pour Baudry, le gouvernement d'entreprise est « l'ensemble des moyens par lesquels les fournisseurs de capitaux de la firme s'assurent de leur rentabilité » (Baudry 2003).

Quant à Charreaux, il définit le gouvernement d'entreprise comme étant « l'ensemble des mécanismes qui ont pour effet de délimiter les pouvoirs et d'influencer les décisions des dirigeants, autrement dit qui gouvernent leur conduite et délimitent leur pouvoir discrétionnaire » (Charreau 1997).

C'est à la suite des scandales de gouvernance dans les années 1990/2000 qu'est né le concept de gouvernement d'entreprise. La chute d'Enron, de Worldcom ont révélé ce que l'exercice abusif du pouvoir au sein d'une entreprise pouvait causer comme dégât (Finet 2005).

En réaction donc à la situation, la gouvernance d'entreprise est venue protéger les intérêts des actionnaires en minimisant et contrôlant les conflits d'intérêts engendrés par la délégation du pouvoir des actionnaires aux gestionnaires de l'entreprise (conseil d'administration et direction générale).

Mais, dans la continuité de cet objectif, il s'est avéré nécessaire de concilier les exigences des parties prenantes (salariés, fournisseurs, sous-traitants, consommateurs, citoyens…) avec les exigences financières des actionnaires.

C'est dans ce cadre que s'inscrit la RSE. Il s'agit d'un concept dans lequel les entreprises intègrent volontairement les préoccupations sociales, environnementales et économiques dans leurs activités commerciales

et dans leurs interactions avec les parties prenantes (Livre vert 2001). C'est la contribution des entreprises aux enjeux du développement durable .

Partant de là, les deux concepts (GE et RSE) entretiennent des rapports étroits. Ce lien n'est plus à démontrer. Plusieurs recherches ont confirmé cette parenté. Par contre, la question qui se pose est relative aux véritables incidents des deux notions sur le processus décisionnel, surtout si l'on prend en considération le fait que le GE fait référence au hard law parce que prévu par des règles juridiques dont la violation entraine une sanction, alors que les questions de la RSE relèvent du soft law répondant à des engagements volontaires (Cuzacq Nicolas 2012).

Autrement dit, notre problématique, qui se limite à la société anonyme marocaine, se scinde en deux questions :

- Quelle est la situation du conseil d'administration aux prises avec la notion de gouvernement d'entreprise ?
- Quel est le rôle des administrateurs relativement à la notion de RSE ? leur fonction est-elle plus exigeante ? Ne va-t-on pas vers une instauration légale de la RSE ?

Notre analyse part du constat que les implications du GE et de RSE sont mal comprises, parfois même ignorées par les entreprises tant en termes de risques que de création de valeur potentielle. Nous essaierons donc à travers ce modeste travail de rassembler les éléments épars formés par l'ensemble des exigences en matière de GE et de RSE.

Dans une première partie, nous présenterons la nouvelle architecture du conseil d'administration aux prises avec la notion de gouvernement d'entreprise et les différentes missions et responsabilités qui en découlent.

Dans une deuxième partie, nous mettrons l'accent sur les exigences supplémentaires découlant de la RSE, et qui sont dictées par la pression des parties prenantes et par l'intervention de plus en plus grande du législateur.

Première partie : Le conseil d'administration aux prises avec la notion de gouvernement d'entreprise

La société anonyme au Maroc a été pendant longtemps régie par le dahir de 1922 qui a rendu applicable dans notre pays la loi française de 1867. Cette loi est devenue archaique, anachronique et totalement décalée par rapport aux réalités politiques, économiques et sociales de notre pays. Le changement est alors opéré par la loi 17-95 modifiée et complétée par la loi 20-05.

Cette dernière a introduit des innovations importantes au niveau du conseil d'administration en rapport avec le concept de gouvernement d'entreprise. En effet, à côté d'une nouvelle détermination des fonctions et missions de l'organe de gouvernance, elle a introduit la faculté de dissociation entre les fonctions de président du conseil d'administration et celles de directeur général.

Parag 1 : Clarification des fonctions et missions de l'organe de gouvernance

Aujourd'hui, le conseil d'administration a un large pouvoir. Ce dernier impose une indépendance de l'organe de gouvernance tant vis-à-vis de la direction de l'entreprise que de ses actionnaires.

A- Le conseil d'administration a un large pouvoir :

Jusqu'à la réforme introduite par la loi 20-05, les missions et pouvoirs des dirigeants des SA et du conseil d'administration se confondaient. La duplication de la définition des pouvoirs résultait des formulations des articles 69 déterminant les pouvoirs du conseil d'administration et 74 pour le président du conseil d'administration tous deux disposant des pouvoirs les plus étendus pour agir en toute circonstance au nom de la société.

Aujourd'hui, les missions du conseil d'administration sont plus claires. En effet, l'article 69 de la loi 17-95 tel qu'il a été modifié par la loi 20-05 dispose que :

« Le conseil d'administration détermine les orientations de l'activité de la société et veille à leur mise en œuvre. Sous réserve des pouvoirs expressément attribués aux assemblées d'actionnaires et dans la limite de l'objet social, il se saisit de toute question intéressant la bonne marche de la société et règle par ses délibérations les affaires qui la concernent. Le conseil d'administration procède aux contrôles et vérifications qu'il juge opportuns ».

Partant de cet article, la loi confère au conseil d'administration trois missions :

-Il détermine les orientations de l'activité de la société et veille à sa mise en œuvre. Il se voit donc reconnaitre le droit de participer à l'élaboration de la stratégie de la société, ses plans d'actions, sa politique de risques, ses budgets annuels et programmes d'activités, et de s'assurer qu'ils seront suivis par la direction générale.

-Il se saisit de toute question intéressant la bonne marche de la société et règle par ses délibérations les affaires qui la concernent. Le conseil d'administration a donc le devoir de s'intéresser de prés à l'activité quotidienne de l'entreprise.

Dans cet axe, l'organe de gouvernance sera chargé de recruter les principaux dirigeants, de déterminer leurs rémunérations et veiller à ce qu'elles soient adaptées et transparentes en vue d'être admissibles et acceptées par les actionnaires, suivre leurs activités et leurs performances et , le cas échéant, les remplacer et préparer les plans de succession.

L'organe de gouvernance s'occupe aussi de surveiller et de gérer les conflits d'intérêt entre la direction, les membres du conseil et les actionnaires, y compris les abus des biens sociaux ou les abus commis dans le cadre des conventions réglementées.

-Il procède aux contrôles et vérifications qu'il juge opportuns. Dans ce cadre, le conseil d'administration est tenu de vérifier la transparence de la gestion, les performances de l'entreprise, l'intégrité de ses systèmes de comptabilité et de communication financière ou non financière.

De même, il lui revient de vérifier si les principes comptables sont respectés, et si les dispositifs de contrôle interne et de maîtrise des risques existants sont adéquats. L'organe de gouvernance se charge aussi de l'organisation de l'audit externe et les relations avec les auditeurs externes.

Le conseil d'administration surveille également le processus de diffusion de l'information et de communication de l'entreprise, notamment en ce qui concerne : les obligations légales et réglementaires en matière d'information ; les orientations stratégiques ; la politique sociale ; la politique d'endettement et de dividendes ; les conventions réglementées avec notamment les principaux dirigeants et les holdings ; la rémunération des dirigeants.

Pour l'accomplissement de ces différentes tâches, le conseil d'administration a le droit de s'informer par lui-même et peut demander à tout moment, s'il l'estime nécessaire, des informations complémentaires même en dehors des conseils. Ce droit à l'information du conseil porte non seulement sur les points prévus à l'ordre du jour mais aussi sur l'ensemble des informations permettant d'apprécier la situation de l'entreprise.

B- L'indépendance du conseil d'administration

Comme il a déjà été signalé, la tâche principale de l'organe de gouvernance est d'évaluer les performances des dirigeants et de prévenir les conflits d'intérêt. Or, la réalisation de cet objectif nécessite une indépendance de l'organe de gouvernance vis-à-vis de la direction de l'entreprise.

Cette indépendance s'apprécie au niveau de la composition du conseil d'administration. En effet, une place doit être accordée aux administrateurs non exécutifs et aux comités spécialisés.

Un administrateur non exécutif est celui qui ne détient pas de fonctions exécutives ou de management dans l'entreprise. Il est considéré comme indépendant, c'est-à-dire qu'il est un membre libre d'intérêt contribuant par sa compétence et sa liberté de jugement à la capacité du conseil à exercer ses missions. Autrement dit, pour pouvoir être qualifié d'indépendant, le membre du conseil ne doit pas se trouver dans une situation susceptible d'altérer son indépendance de jugement ou de le placer dans une situation de conflit d'intérêts réel ou potentiel.

Cette notion est la transposition du modèle anglo-saxon, celui de l'independent non executive director. Elle est apparue avec la critique du contrôle exercé par le conseil. Elle est la marque d'une méfiance à l'égard des administrateurs dirigeants qui perdent facilement l'idée de démocratisation de la société au profit de ses actionnaires.

Partant de là, les administrateurs non dirigeants ont une mission de contrôle qui consiste à s'assurer que le management se conformait à certains standards de conduite et que la comptabilité est régulièrement tenue. Ils doivent porter un regard objectif sur l'entreprise, contribuer à enrichir la réflexion et la prise de décision grâce en

particulier à leur assiduité, à leur profession et à leur indépendance. A cet effet, l'entreprise doit mettre à leur disposition la formation, l'information et les moyens nécessaires à l'exercice efficace de leur mission.

Ces administrateurs non dirigeants peuvent constituer entre eux des comités spécialisés. Sur ce point, le code de bonne gouvernance recommande de créer au moins deux comités différents à savoir un comité d'audit et un comité de nomination et de rémunération des dirigeants. L'organe de gouvernance jugera de l'opportunité de s'adjoindre d'autres comités (risques, investissement..).L'expérience montre que le rôle de ces comités est essentiel puisqu'ils traitent indépendamment du conseil d'administration certains aspects de l'administration de la société comme la rémunération des dirigeants, la réalisation d'audit, l'aspect stratégique, les questions de nomination des administrateurs et dirigeants.

Toujours dans le souci d'assurer cette indépendance, le code de bonne gouvernance déconseille les mandats réciproques, pratique selon laquelle les dirigeants d'une société sont les membres de l'organe de gouvernance d'une autre société et réciproquement ; cette pratique fait que les administrateurs ne sont pas incités à pratiquer un vrai contrôle dans la société afin de ne pas être symétriquement contrôlés dans la société qu'ils dirigent.

Il est par ailleurs recommandé d'éviter un cumul de mandats de nature à altérer l'exercice de la fonction de membre de l'organe de gouvernance dans les meilleures conditions.

Parag 2 : Choix de maintenir le cumul des fonctions de président et de directeur général ou de les dissocier

La loi 20-05 a introduit le choix entre deux formules : soit la dissociation des fonctions de président du conseil d'administration et de directeur général, soit le cumul des deux fonctions sous le titre de président directeur général.

Le choix du conseil d'administration sera porté à la connaissance des actionnaires lors de la prochaine assemblée générale et fera l'objet des formalités de dépôt, de publicité et d'inscription au registre du commerce dans les conditions prévues par la loi.

A-Dissociation des fonctions

La dissociation des fonctions de président du conseil d'administration et de directeur général constitue sans aucun doute l'un des aspects majeurs de la réforme entreprise par le législateur marocain. Elle reflète la grande influence des thèses d'origine anglo-américaine de gouvernement d'entreprise visant une plus grande responsabilisation des dirigeants des sociétés anonymes et un meilleur équilibre des pouvoirs entre le conseil d'administration doté d'un président, et le directeur général.

Conformément à la loi20-05, le président du conseil d'administration représente le conseil d'administration. Il organise et dirige les travaux de celui-ci, dont il rend compte à l'assemblée générale. Il veille au bon fonctionnement des organes de la société et s'assure en particulier que les administrateurs sont en mesure de remplir leur mission

Quant au directeur général. il est investi des pouvoirs les étendus pour agir en toute circonstance au nom de la société. Il représente la société dans ses rapports avec les tiers. C'est lui qui dirige opérationnellement l'entreprise, et en contrepartie est responsable devant le conseil d'administration et assume la responsabilité civile du chef d'entreprise. Il doit veiller en particulier à transmettre au président toutes les informations qu'il juge utiles pour que le conseil d'administration soit correctement informé. Dans la limite de l'objet social, et sur autorisation du conseil, il a le pouvoir de donner des cautions, avals et garanties. Le directeur général peut également demander au président la convocation d'une assemblée générale.

Comme on peut le constater, il existe une sorte de subordination du directeur général par rapport aux représentants des actionnaires. Le but du législateur est de permettre au président du conseil d'administration de faire contrepoids au directeur général et d'éviter toute omnipotence de sa part. C'est d'ailleurs pour cette raison que nombre d'auteurs ont estimé favorable une telle séparation des fonctions (R.Kosnic (1987)).

B- Le cumul des fonctions

La décision du conseil d'administration de confier la direction générale de la société à son président a pour conséquence de concentrer entre les mains de celui-ci deux sortes de pouvoirs : ceux propres au président du conseil d'administration et ceux confiés au directeur général (Y.Guyon 1993).

Cette formule présente des inconvénients dans la mesure où le dirigeant cumulant le rôle de président du conseil et de directeur général s'érige en acteur incontournable à travers son rôle dans la fixation de l'ordre du jour du conseil (J.Harrison, D.Torres et S.Kukalis (1988)), au travail des divers comités spécialisés, à la réunion et au déroulement des assemblées générales. Il peut donc réduire l'efficacité du contrôle du conseil. (R.Beatty,E.Zajac (1994)).

On se demande donc si le législateur marocain a offert le choix juste pour ne pas brusquer les habitudes dans l'intention de ne garder par la suite que la dissociation des fonctions, suivant sur ce point les pas de son homologue français.

On conclut donc que le gouvernement d'entreprise introduit plusieurs exigences à l'égard des administrateurs en tenant compte des intérêts des actionnaires, qui en tant qu'opérateurs de marché, apportent leur capital et attendent des résultats qui supposent de la part des dirigeants un comportement apte à assurer une bonne gestion de la société. Qu'en est-il de la RSE ? La fonction des dirigeants, risque t -elle de devenir encore plus exigeante ?

Deuxième partie : La RSE et les exigences supplémentaires

Comme nous l'avons déjà définie, une entreprise socialement responsable est celle qui s'engage, au-delà de ses obligations légales, à considérer de manière systématique les différents intérêts qui sont affectés par son fonctionnement afin d'obtenir le meilleur impact de ses activités sur ses travailleurs, ses partenaires et sur le développement durable de manière générale.

Il s'agit donc d'une démarche volontaire impliquant des engagements libres de la part des dirigeants, et à ce titre, on peut penser légitimement que la RSE n'entraine pas d'exigences supplémentaires à la fonction des administrateurs.

Mais, lorsqu'on considère la finalité même de la RSE et qui est la prise en considération des intérêts des parties prenantes, on pense automatiquement à la pression que ces dernières peuvent exercer sur les entreprises, faisant diminuer l'aspect volontaire de la RSE. Constat accentué encore plus par l'encadrement juridique de la RSE.

Dés lors, se pose la question de savoir quel est le rôle des administrateurs à cet égard ? Les modes de management doivent-ils associer étroitement la RSE au pilotage stratégique ? Ou encore quelles sont les véritables incidences de la RSE sur le processus décisionnel des sociétés ?

Parag 1 :L'influence des parties prenantes sur le processus décisionnel

Avec la notion de RSE, les administrateurs se trouvent sur un territoire plus large de gouvernance occupé non seulement par les actionnaires, mais par toutes les parties prenantes (Stakeholders) (Freedman et Market 1984).

Ces dernières regroupent l'ensemble de ceux qui participent à la vie économique (salariés, clients, fournisseurs…) de ceux qui observent l'entreprise (les syndicats, les ONG) et de ceux qu'elle influence plus ou moins directement (société civile, collectivité locale). Autrement dit, les parties prenantes sont toutes les personnes ayant un intérêt dans les activités de l'entreprise (A.Mullenbach 2007).

Ces parties prenantes exercent sur l'entreprise plusieurs pressions d'ordre social, environnemental et économique, qui la poussent à intégrer dans sa stratégie managériale les principes de la RSE, encore encouragée dans cette voie par la médiatisation de certains procès et le caractère stratégique de l'image de marque dans un marché de plus en plus concurrentiel.

Voilà pourquoi certaines pratiques dites de RSE se sont développées, certaines entreprises décidant de doter leurs produits ou leurs services de labels sociaux ; d'autres prenant des engagements publics ou finançant des initiatives de type caritatif qui les mènent ensuite à communiquer.

Les exemples sur le plan international caractérisant la pression des parties prenantes sont nombreux. On peut prendre celui de Nike INC.

Dans les années 1996-1997, Nike a vu sa réputation entachée car elle avait recours à une sous-traitance étrangère ayant une législation peu éthique. En 1997, la photo d'un enfant pakistanais en train de coudre un ballon Nike apparait au public. Les médias, les ONG, les lobbies, les syndicats, les consommateurs… s'acharnent sur la marque et de nombreuses actions sont menées contre la marque. En 1998, Nike assiste à une chute considérable de ses résultats.

Devant cette situation, Nike devait réagir et adopter un nouveau modèle d'organisation de la sous-traitance. Dans ce cadre, de nombreux engagements en rapport avec la RSE ont été pris par les dirigeants. En effet, ces derniers décident de payer les ouvriers au dessus de la moyenne des pays où étaient basées les usines. Ils ont édicté également un code de conduite et ont confié au cabinet Price Watherhouse Cooper (PWC) la mission d'auditer chaque année ses sous-traitants pour vérifier l'application du code de conduite. De même, Nike a confié à sept universités le soin d'établir un rapport sur les conditions de travail dans les usines de la firme. Finalement, Nike s'implique dans une politique environnementale. A titre d'exemple, l'entreprise récupère et recycle les vieilles chaussures.

Le cas de Nike, étudié par Gasmi et Grolleau (2005) montre bien l'évolution des stratégies adoptées par la multinationale face à l'émergence et au développement des critiques relatives à ses sous-traitants.

C'est pour éviter des histoires comme celle de Nike, et cette pression des parties prenantes qui peut être négative, et pour anticiper les contraintes et prévenir les risques, que plusieurs entreprises marocaines ont intégré dans leur stratégie managériale la démarche RSE.

Ces entreprises marocaines ont compris que l'application de la RSE améliore les mesures de précaution et de prévention contre les accidents industriels ou économiques, les risques sociaux, les risques juridiques, les grèves ainsi que tout problème menaçant la réputation et la performance de l'entreprise. Il s'agit donc pour l'entreprise de relever trois défis à savoir un défi managérial, économique et environnemental (Supized 2002, Igalens 2012).

Le processus d'intégration de la RSE dans la stratégie de l'entreprise comporte plusieurs étapes et nécessite un investissement matériel et humain. Mais, d'une manière générale, il est attendu du conseil d'administration d'assimiler les éléments fondamentaux composant les grandes thématiques de la RSE, d'identifier parmi ces thématiques celles qui lui paraissent les plus importantes pour l'entreprise selon le secteur d'activité en distinguant entre celles porteuses de dangers et celles qui recèlent des opportunités, de procéder à l'élaboration de la stratégie opérationnelle de l'entreprise qui prend en compte les attentes des parties prenantes, de rendre compte de sa conduite à cet égard tant aux parties prenantes qu'à l'opinion publique.

Chaque entreprise intègre donc une démarche générale RSE tout en insistant sur les axes les plus importants pour son activité et les inclut dans sa stratégie décisionnelle. C'est ce qui est appliqué par plusieurs entreprises marocaines.

On peut prendre deux exemples d'entreprises opérant dans des secteurs différentts : cas de Managem (Rapport développement durable 2014) et celui de Jet Sakane.

Managem est une société anonyme, c'est un acteur marocain dans le secteur des mines et de l'hydrométallurgie. Il opère depuis plus de 85 ans dans l'extraction, la valorisation et la commercialisation des métaux de base, des métaux précieux, du cobalt et d'autres minerais au Maroc et en Afrique.

Le groupe Managem a intégré la démarche RSE qui l'a placé dans le palmarès des top performers RSE 2015. Cela vient la récompenser pour ses performances en matière de renforcement des compétences et de l'employabilité, le respect du dialogue social, la préservation de la santé et de la sécurité, la contribution au développement des communautés et la promotion de la bonne gouvernance et de l'éthique, la préservation de l'environnement.

Dans ce dernier axe (préservation de l'environnement), les ambitions de Managem sont fortes. Le groupe vise à réduire son empreinte carbone en baissant de 5% à 10% la consommation annuelle de chacun de ses sites, à valoriser les rejets mineurs en ressources.

Signalons qu'en 2013, le complexe industriel de Guemassa a démarré l'exploitation de son usine d'acide sulfurique dont le processus industriel permet de valoriser les rejets de la mine de Guemassa en nouveaux produits destinés à la commercialisation tout en produisant de l'energie propre pour le site.

Le deuxième cas est celui de Jet Sakane spécialisé dans la promotion immobilière. Cette entreprise a pour ambition la mise en valeur de ses travailleurs à travers la liberté syndicale, la parité entre les sexes, la formation, le dialogue social, la sécurité et la santé au travail, la prévention des accidents de travail et de maladies professionnelles…

Les préoccupations pour l'environnement et le bien être des clients sont au cœur de la stratégie de l'entreprise. Ses ensembles immobiliers réservent 30% des supérficies aux espaces verts et prévoient des équipements

sociaux et collectifs. La gestion décennale de la copropriété lui permet d'y déployer des actions à caractère social : cours d'alphabétisation et d'informatique, les crêches, les cours de soutien scolaire et bien d'autres.

L'exemple de ces deux entreprises illustre leur fort engagement envers leurs collaborateurs, leurs clients, leurs partenaires…Cet engagement touche la gouvernance puisque toutes les solutions, toutes les actions se situent finalement au niveau des décisions qui doivent être prises en ce qui concerne la recherche de l'équilibre entre les intérêts des actionnaires et ceux plus vastes de la collectivité.

Parag 2 : Encadrement juridique de la RSE

La démarche RSE à l'origine volontaire s'est traduite peu à peu par des impératifs juridiques adoptés par le législateur.

En effet, aujourd'hui il ya un grand débat sur la question de l'institutionnalisation de la RSE, de sa fondamentalisation, du passage du volontarisme à la coercition, de la justiciabilité renforcée de la RSE (I.Desbarats 2008)…La question est à notre sens très importante. Nous avons déjà déterminé comment la pression des parties prenantes fait sortir la RSE de son cadre volontaire. Si l'on rajoute à cet aspect celui purement juridique, la coercition risque de bousculer encore plus le volontarisme.

Au Maroc, le cadre juridique s'est progressivement modifié pour tenir compte de l'adhésion aux valeurs de la RSE.

C'est ainsi qu'en matière de la législation du travail, on assiste à l'entrée en vigueur en 2004 du code de travail qui précise les principes de base à respecter : mesures relatives à la santé et à la sécurité au travail, au licenciement, à la durée du travail, au travail des enfants, au salaire minimum, aux jours de repos…Par ailleurs, ce code propose des instruments pour l'adaptation de certaines mesures aux spécificités sectorielles et organisationnelles : règlement interne, comité d'entreprise, comité d'hygiène et de sécurité, convention collective…

D'autres aspects laissés auparavant à la discrétion de l'entreprise ont fait l'objet de réglementation. C'est ainsi que dans le cadre de son adhésion aux principes du développement durable et à la RSE, le Maroc s'est doté d'un cadre législatif relativement complet pour la protection de l'environnement et la gestion des ressources naturelles.

On peut citer dans ce cadre la loi 11-03 relative à la protection et à la mise en valeur de l'environnement. Elle a pour objet d'édicter les règles de base et les principes généraux de la politique nationale dans le domaine de la protection et de la mise en valeur de l'environnement.

Cette loi comporte plusieurs dispositions relatives à la protection de l'environnement et des établissements humains, à la protection de la nature et des ressources naturelles, aux pollutions et nuisances, aux instruments de gestion et de protection de l'environnement, à la procédure et la poursuite des infractions…Toutes les entreprises sont tenues de respecter cette loi dans toutes ses dispositions, de s'y conformer dans leur conduite, et de les introduire dans leur politique de management environnemental.

Cette législation trouve son prolongement dans la loi 13-03 relative à la pollution de l'air, ainsi que dans la loi 12-03 relative aux études d'impacts sur l'environnement et la loi 28-00 relative à la gestion des déchets et leur élimination. Ces trois lois ont le même objet. Elles sont toutes animées d'un esprit de participation et d'ouverture aux meilleures pratiques environnementales.

Par ailleurs, le Maroc a adopté la loi-cadre 99-12 portant charte nationale de l'environnement et du développement durable. Cette loi fixe les objectifs fondamentaux de l'action de l'Etat en matière de protection de l'environnement. Elle prévoit des dispositions s'appliquant aux entreprises privées et publiques exerçant une activité industrielle et commerciale. Ces dernières doivent adopter des mesures d'approvisionnement, d'exploitation et de production répondant aux exigences du développement durable, évaluer périodiquement l'impact de leurs activités sur l'environnement et s'engager à réduire les effets négatifs.

D'autres mesures très importantes sont prévues par cette loi :

-La mise en place d'un système d'évaluation environnementale stratégique permettant d'apprécier la conformité des politiques, des stratégies, des programmes et des plans de développement aux exigences de la protection de l'environnement.

-L'application de taxes écologiques et des redevances aux activités caractérisées par un niveau élevé de pollution et de consommation de ressources naturelles, portant ainsi préjudice à l'environnement.

-Institution d'un système d'écolabel visant à promouvoir les produits ou services ayant un impact réduit sur l'environnement et ceux qui se conforment aux exigences du développement durable.

Comme on peut le constater, la RSE perd de son aspect volontaire pour entrer progressivement dans la réglementation juridique s'imposant d'une manière plus forte aux administrateurs qui se trouvent donc dans l'obligation de l'intégrer dans l'organisation stratégique de l'entreprise.

Passé donc l'effet de mode, la RSE devient un levier de compétitivité pour les entreprises, et à ce titre elle a toutes les raisons de figurer au premier rang des préoccupations des administrateurs.

Consciente de ce rôle dévolu à la RSE, la confédération générale des entreprises du Maroc a mis en place le label CGEM pour la RSE qui est une reconnaissance solennelle du respect par les entreprises du Maroc de leur engagement à observer, défendre et promouvoir les principes universels de responsabilité sociale et de DD dans leurs activités économiques, leurs relations sociales et plus généralement dans leur contribution à la création de valeurs. Par cette initiative, on entend encourager les entreprises respectueuses de leur engagement structuré autour de 9 axes :

Respecter les droits humains ; améliorer en continu les conditions d'emploi et de travail ; protéger l'environnement ; prévenir la corruption ; respecter les règles de la saine concurrence ; renforcer la transparence du gouvernement d'entreprise ; respecter les intérêts des clients et des consommateurs ; promouvoir la responsabilité sociale des fournisseurs et sous-traitants ; développer l'engagement sociétal. Plusieurs partenaires se sont associés à la confédération pour promouvoir le label CGEM. Ces partenaires (l'administration des douanes et impôts indirects, la CNSS, le crédit agricole, le groupe Banques Populaires, la BMCI et la direction générale des impôts) octroient aux entreprises labellisées des avantages et traitements spécifiques (tarification préférentielle, simplification des procédures, assouplissement des contrôles, gestion personnalisée, célérité dans le traitement des dossiers…) (15).

Conclusion

De cette étude, on peut conclure qu'aujourd'hui, la tâche des administrateurs ne cesse de devenir encore plus exigeante. S'il ya bien une convergence entre les deux notions (gouvernement d'entreprise et RSE), chacune conduit les administrateurs à plus de vigilance et à plus de responsabilisation.

La RSE vient s'ajouter au concept de gouvernement d'entreprise pour être l'une de ses composantes essentielles : une bonne gouvernance d'entreprise nécessite l'intégration de la RSE. Il s'agit donc d'une question organisationnelle stratégique qui requiert une surveillance étroite de la part du conseil.

Or, et jusqu'à nos jours, si la plupart des administrateurs connaissent la notion de RSE, nombreux sont ceux qui veulent savoir quel est leur rôle à cet égard.

Aujourd'hui, il devient urgent de mobiliser les administrateurs sur les questions de RSE et de faire en sorte qu'elles soient intégrées aux grandes orientations stratégiques des conseils d'administration.

The Effect of the Country of Origin on the Romanian Consumers' Opinions and Purchase Decision

Anca Tamaş, Bucharest University of Economic Studies, Romania, anca.tamas@rei.ase.ro

Abstract

The aim of this paper is to investigate if the reputation of the country of origin of the wine influences the opinions of the consumers and the purchase decision. Statistical analyze and econometric methods were used, using SPSS: frequency distributions, factor analysis, ANOVA and linear regression. Critical assessment of literature review was made. The author used quantitative methods: 214 questionnaires. There is a strong correlation between the country of origin of the wine and the perceived quality of the wine for consumers, winemakers and Masters of wine; the country of origin cues become more important than the wine cues in the purchase decision. As practical implications, the study found different correlations for consumers' opinions, buying attitudes and purchase decisions. The original element is using Romanian and international wine consumers in a real buying situation; the opinions of Romanian winemakers and of international Masters of wine is an added value due to their expertise.
As limitation, the number of respondents is limited.

Keywords: country of origin effect

I. Literature review

In the literature review body, we can identify two major directions: general country of origin effect regarding wine-similar to country of origin effect regarding any other product durable or non-durable and specific country of origin effect regarding wine only.

The general effect includes: quality assessment, consumer perceptions, information processing, decision making, consumer preferences, purchasing decision, price.

The specific country of origin effect regarding wine only refers to country of origin as an extrinsic wine cue, wine labels, wine range, wine consumers, domestic versus foreign wines.

I.1. Extrinsic cue

Intrinsic cues of the wine such are taste and aroma cannot be usually evaluated by consumers during the buying decision process, or be assessed by visual inspection of the wine in the store, and many consumers take little or no effort for external search before entering the store (Chaney, 2002). Even when these intrinsic information are available, like actual tastings, consumers rely on the origin of the wine in decision making process. (Halstead, 2002), (Goodman, Lockshin and Cohen, 2007), (Veale and Quester, 2008)

Therefore, extrinsic cues and mainly country of origin or region of origin are most important for consumers.(Samiee, 1994), (Nebenzahl, Jaffe and Lampert, 1997)

Although extrinsic cues have no direct bearing on the quality of wine, consumers used them as indirect indicators or substitutes for intrinsic cues(Bilkey and Nes, 1982) or assign a meaning to an entire wine class(Goldberg and Baumgartner, 2002). Country of origin information, price and brand might be used by consumers as extrinsic factors in quality assessment. (Hu *et al.*, 2008)

I.2. Wine labels

Labels are relevant in buying decision of wine for home, party, bar/restaurant consumption for all the consumers (Wolf and Thomas 2007) and especially for wine novices. (Boudreaux and Palmer, 2007). Consumers between 21 and 40 years old found wine labels more intimidating than consumers over 60. Consumers under 30 prefer more creative labels (Qenani-Petrela, Wolf and Zuckerman, 2007) and women use color, image and logo as indicators of purchasing intents more than men do. (Barber, Almanza and Donovan 2006)

There is a positive relationship between label attractiveness, eye-catching properties and buying decision(Wolf and Thomas, 2007). Consumers rated country of origin as the most important attribute of the label(Barber, Almanza and Donovan 2006), although images and colors on the label have strong effects as well.(Boudreaux and Palmer, 2007)

Wine labels are considered a risk reduction strategy (Skuras and Vakrou, 2002) and more reliable compared to wine publications. (Barber, Almanza and Donovan 2006)

I.3. Wine range

Hansard(2010) emphasized the relationship between country of origin of wine and wine range. Quality is crucial for Top Range wines, as well as for Medium range wines. Price is critical for Entry Level, as well as for Medium Range wines. What matters most apart from quality and price is price stability and quality consistency both for Entry Level and Medium Range wines and price/quality ratio for Medium Range wines. For bulk wines, price and size of supply volumes are the most important. Country of origin or region of origin matters most for Top Range wines and Medium Range wines.

I.4. Wine consumers

It all depends on what kind of consumer you are: for non-wine connaisseurs knowing the country or region of origin makes buying easier, for new consumers intrinsic attributes got a great importance (Thomas and Pickering, 2003), for less experienced consumers medals cue are important (Orth, 2002), for less frequently buyers price is very important(Batt and Dean, 2000), for frequently buyers brand is the most important(Batt and Dean, 2000), for wine connaisseurs the wine company, wine brand and experts' opinions on wine matters most(Thomas and Pickering, 2003) and for wine experts country or region of origin matters most. (Rasmussen and Lockshin, 1999)

I.5. Domestic versus foreign wine

Often, if the country of origin of the wine is a developed country or a known wine making, this is considered to be a quality insurance, while if the country of origin of the wine is a less developed country or a less known wine making, the quality of the wine is considered lower. (Kaynak, Kucukemiroglu and Hyder, 2000)

French wines are considered to be expensive, but too dry and rough, Italian wines are considered of a lower quality compared to French ones, yet a better value for the money, Spanish wines are considered cheap and rough, German wines are considered to be safe and reliable(Gluckman, 1990). Canadian wines are perceived of a lower quality comparing to French, Italian, Spanish and German wines. (Wall and Heslop, 1986)

The quality of the Romanian wines significantly improved after the communist period, having France as a model in wine strategy. (Jubénot, 2014)

II. The aim and the hypothesis

The aim of this paper is to investigate if the reputation of the country of origin of the wine influences the opinions of the consumers and the purchase decisions.

The research hypothesis are:
H1: The information regarding the country of origin of the wine matters in the purchase decision.
H2: The reputation of the country of origin of wine influences the buying attitude of the consumers.
H3: The perception of the consumers on the reputation of the country of origin of the wine depends on the perception of the consumers on the reputation and the price of the wine.
H4: Country of origin of the wine is the most important extrinsic cue for the purchase decision of the consumers regarding the wine.
H5: The opinions of the consumers and the masters of wine regarding the reputation of the country of origin of wine are convergent.

III. Methodology

III. 1. The Sample

Sample of respondents consist of four groups, Romanian consumers-RC, international consumers-IC, Romanian winemakers, International Masters of wine, as follows: 52 RC in real buying circumstances during an International Wine Fair held in Bucharest in December 2015; 51 IC also in real buying circumstances in London and Madrid. The IC were participants at two international conferences held in London and in Madrid, same as the author and the questionnaires were filled in the evening before leaving by those participants who actually bought wine as a gift for families and friends. All the consumers were asked to fill in the questionnaires after buying at least a bottle of wine. 52 Romanian winemakers during the above mentioned Wine Fair and 59 Masters of wine who filled in the questionnaires in January 2016 by email. For opinions, beliefs, assessing quality, any kind of consumer could be used in a research, yet for intention to buy or purchase decision, real buyers would be more appropriate, because they can refer to an actual decision or intention, instead of a potential one. Apart from the opinions of the consumers, the opinions of winemakers and Masters of wine are considered an added value due to their specific expertise.

III. 2. The methods

Quantitative methods were used, namely questionnaires, in Romanian for RC and winemakers and in English for IC and Masters of wine. To analyze the questionnaires, frequency distribution, factor analysis, ANOVA, linear regression in SPSS were used.

Therefore for this study the consumers are men or women(in similar proportions), mainly between 25 and 34 years old for IC and between 35 and 50 years old for RC, seeing themselves as having an average income, buying mainly when needed for IC and occasionally for RC, mainly for a celebration for IC and for themselves for RC. IC were from: Algeria, Bulgaria, Colombia, Czech Republic, Germany, Hungary, India, Italy, Jordan, Korea, Nigeria, Poland, Portugal, South Africa, Slovakia, Slovenia, Spain, Thailand, Turkey, UK, USA and the country of origin of the wine they have bought was: Australia, Bulgaria, Chile, France, Germany, Italy, Moldavia, Portugal, South Africa, Spain, UK. The country of origin of the wine bought by RC was: France, Germany, Moldavia, Portugal, Romania.

Out of the 52 Romanian winemakers, 18 work for less than 5 years in this business(34.61%), 14 are in the business for 5 to 10 years(26.92%), 12 for 10 to 20 years(23.07%) and 9 for more than 20 years(17.30%). Their jobs in the wineries they represent are: brand manager(2), commercial manager(2), export manager (1), internship(1), Master of wine OIV(1), marketing manager(4), oenologist(6), PR manager(1), sales manager(10), sommelier (5), Weset level 2(1), wine manager and promoter(4), wine seller(5), wine specialist(2), winemaker(9). Apart for being Master of wine, the 59 Master who were kind to fill in the questionnaires are also involved in wine consulting, wine education, journalism, wine buying, wine import and export, wine selling, some of them have own wineries or are winemakers. Only 2 out of 59 are Masters of wine for less than 5 years and only 3 are Masters of wine for 5 to 10 years, 15 of them are Masters of wine for 10 to 20 years and the rest of 38 for more than 20 years. Both the opinions of the Masters of wine and of the winemakers are valuable due to their great experience.

IV. The findings

IV. 1. The findings regarding the opinions

The consumers were asked to fill in their opinions regarding the following 10 countries : China, France, Germany, Hungary, Italy, Romania, Russia, Spain, UK, USA and the following sentences regarding each of the mentioned countries:
S1: The wines are expensive;
S2: The wines are expensive, but they worth the money;
S3: The wines are famous;
S4: The wines have a high quality;
S5: The wines are available;
S6: The wines are daintiness;
S7: The country is well known for its wines;
S8: The country has a long tradition regarding wines;
S9: The country is a top wine producer;
S10: The country of origin is a guarantee for the quality of its wines.

The 10x10 matrix model was used with countries as lines and sentences as columns and a 7 points Likert scale was chosen with 1 as least important and 7 as most important. The results for consumers are presented in the following table. SPSS was used to compute the means.

Table 1: The means for the opinions of the consumers

Consumers	Country	S1	S2	S3	S4	S5	S6	S7	S8	S9	S10
IC	France	5.76	5.58	5.96	5.74	5.66	5.68	5.92	6.05	5.90	5.94
RC	France	5.82	5.71	6.25	6.13	6.32	6.26	6.32	6.38	6.40	6
IC	Italy	5.09	5.31	5.43	5.50	5.29	5.29	5.33	5.60	5.50	5.29
RC	Italy	5.11	5.03	5.42	5.36	5.53	5.5	5.46	5.51	5.61	5.23
IC	Spain	4.72	5.11	5.09	5.078	5.15	4.82	5.25	5.47	5.31	5.09
RC	Spain	4.80	4.78	5.38	5.23	5.34	5.15	5.38	5.38	5.19	4.94
IC	USA	3.52	3.66	3.25	3.41	3.62	3.29	3.05	3.29	3.23	3.23
RC	USA	3.40	3.53	3.28	3.44	3.32	3.15	3.23	3.05	3.11	3
IC	China	2.70	2.88	2.66	2.66	2.92	2.68	2.43	2.54	2.54	2.78
RC	China	2.57	2.65	2.26	2.55	2.65	2.34	2.13	2.32	2.32	2.23
IC	Germany	4.17	4.13	3.62	3.90	4.07	3.52	3.52	3.70	3.70	3.82
RC	Germany	3.69	3.36	3.23	3.32	3.40	3.21	3.09	3.30	3.13	3.21
IC	Hungary	3.54	3.76	3.54	3.54	3.70	3.54	3.17	3.41	3.45	3.49
RC	Hungary	3.48	3.40	3.26	3.44	3.53	3.30	3.26	3.26	3.17	3.05
IC	Russia	3.47	3.50	3.11	3.33	3.45	3.05	2.823	2.96	3.07	3.27
RC	Russia	3.13	3.19	3	2.82	3.03	2.82	2.71	3.019	2.67	2.75
IC	Romania	3.25	3.52	3	3.25	3.33	3.09	2.80	3.27	3.11	3.01
RC	Romania	3.82	4.28	4.51	4.69	4.30	4.76	4.34	4.76	4.15	4.11
IC	UK	4.66	4.56	4.01	4.33	4.31	4.098	3.76	4.01	3.88	4.09
RC	UK	3.71	3.42	3.21	3.15	3.19	2.86	2.73	3.17	2.88	3.01
IC	Overall means	4.09	4.20	3.97	4.07	4.15	3.91	3.80	4.03	3.97	4.00
RC	Overall means	3.95	3.94	3.98	4.01	4.06	3.94	3.86	4.02	3.86	3.75

The sentences were grouped in COO features(S7-S10) and Wine features(S1-S6) and the averages for the two groups were compared. Both for IC and RC, opinions on wine features matters more than on COO features, yet the difference between the two groups is smaller for IC. The averages for IC are bigger than those for RC for both groups, 4.06 compared to 3.98 for wine features and 3.95 compared to 3.87 for

COO features. Although the differences between means are quite small, we will get a better view by looking at the way the consumers ranked the countries according the 10 sentences.
There is a consistency of ranks for IC, the only changing among sentences is for Romania and Russia, each of holding the eighth place five times and the ninth place five times. For RC, only Germany, Hungary, UK and USA are changing the fifth, sixth, seventh and eighth place among them. When comparing the ranks between IC and RC, we can see that they have the same opinions for top three places: France, Italy, Spain, as well as for the last place: China, they also agree for Russia, Hungary and USA for half of the cases.

The winemakers and the Masters of wine expressed their opinions on the following 24 sentences using a 7 point Likert scale from 1 for least important and 7 for most important. SPSS was used for the means of the answers.

Table 2: The winemakers and the Masters of wine scores

Sentence	IC means	RC means
1.It is normal for the wines produced in countries with a solid tradition to be more expensive because they are high quality	3.62069	3.038462
2.For cheap wines the country of origin is of little or no importance	4.155172	4.211538
3.The country of origin is less important for cheap wines compared to expensive wines	5.568966	4.076923
4.For any consumer it is important to know the country of origin when buying wine	4.637931	6.653846
5.The country of origin could be an important information if the wine is not familiar for the buyer.	5.37931	5.903846
6.For a consumer the country of origin matters only if the wine is bought for family or friends.	2.603448	3.211538
7.For high quality wine retailer should display the country of origin of the wine.	6.105263	6.307692
8.For premium wines it is important for retailers to display the country of origin for the wine.	5.931034	6.384615
9.The country of origin is an important information for consumers only for the exclusive wines.	3.034483	4
10. Consumers should not buy a wine if they do not know the country of origin of the wine.	3.333333	4.980769
11. The country of origin of a wine is the most important information for a consumer.	3.206897	4.711538
12.Information regarding to the country of origin of wines could help consumers to choose a wine.	5.660714	4.615385
13.The country of origin of a wine matters in the intention to import wine.	6.051724	5.769231
14. The country of origin of a wine matters in the decision to import wine.	6	5.461538
15. The effect of the country of origin of wines can change in time.	5.862069	4.807692
16. The image of the country of origin of wine matters in promoting wine.	5.896552	5.692308
17.Country of origin of wine guarantees the quality of the wine.	2.155172	4.423077
18.Counry of origin of wine is not a predictor for the quality of the wine.	5.982759	4.826923
19.To find out the quality of the wine it is enough to know the country of origin of the wine.	1.517241	2.596154
20.In your country are foreign wines considered of higher quality compared to national wines.	3.945455	2.5

21.The ethnocentric consumers prefer national wines, regardless of the wine's quality.	4.553571	4.192308
22.The wines produced in developed countries have a higher quality compared to wines produced in developing countries or in less developed countries.	4.210526	3.384615
23.The design of the wine bottle is more important than the country of origin of the wine.	2.877193	4.384615
24.The brand of the wine is more important than the country of origin of the wine.	4.275862	4.423077

The major differences were for sentences 17 and 4 were RC got higher scores, other important differences are for sentences 23, 11, 10, where again RC got higher scores compared to IC, while for sentences 20, 18, 15, 12, 3 IC got higher scores. For the rest of 14 sentences, the differences between IC and RC are not significant.

IV. 2. The opinions of Romanian producers and of the Masters of wine

A factor analysis using SPSS was made for the Masters of wine and for the Romanian winemakers. For the Masters of wine, the highest correlations are for the following pairs of sentences, with the following correlation coefficients: S2 and S3-0.636, S13 and S14-0.866, S17 and S19-0.674. The value of KMO test for measuring the sampling adequacy is 0.538 with Sig=0.000. Eight factors were identified by the analysis, explaining 71.07% of the variance. The first factor "COO and wine quality" explains 17.04% of variance and includes S17 and S19 as initial variables. The second factor "COO and wine imports" explains 15.58% of variance and includes S13 and S14 as initial variables.
For the Romanian winemakers, the highest correlations are for the following pairs of sentences, with the following correlation coefficients: S19 and S20-0.668, S4 and S8-0.613. The value of KMO test for measuring the sampling adequacy is 0.505 with Sig=0.000. Eight factors were identified by the analysis, explaining 70.06% of the variance. The first factor "COO and wine quality" explains 19.08% of variance and include S1, S9, S19, S20 and S22 as initial variables. The second factor, "Importance of COO", explains 12.68% of the variance and includes S4, S7 and S8 as initial variables. The next six factors explains less than 10% of the variance each in either case.

IV. 3. Top countries as seen by the Masters of wine

The Masters of wine were asked to make top 3 countries regarding

A. The best wines they had tasted;
B. The most famous wines in their opinion;
C. With the most expensive wines;
D. With the widely known wine tradition;
E. As successful new players in the wine market;
F. As the main players in the wine market

Table 3: top 3 countries in the opinion of the Masters of wine

Top 3 countries regarding	First place	%	Second place	%	Third place	%
The best wines they had tasted	France	83.6	Italy	47.5	Germany	23
The most famous wines in their opinion	France	100	Italy	77	Spain USA	31.1 31.1
With the most expensive wines	France	96.7	USA	52.5	Italy	50.8
With the widely known wine tradition	France	91.8	Italy	85.2	Spain	63.9
As successful new players in the wine market	New Zeeland	29.5	Chile	24.6	USA	14.8
As the main players in the wine market	France	83.6	Italy	63.9	Spain	39.3

The opinions of Masters of wine regarding all items but E are consistent with the opinions of both IC and RC for France, Italy and Spain. Masters of wine have a higher opinion on Germany than RC and a higher opinion on USA than IC and RC. On item E, the answers were really diverse, including countries from

South America(Chile, Brazil, Argentina), New Zeeland, Australia, South Africa, countries from Europe(Greece, Austria, UK, Hungary, Portugal, Cyprus, Croatia, Romania, Slovenia), countries from North America(USA, Canada), countries from Asia(China, Georgia, Turkey).

IV. 4. The results for the purchase decision

The consumers were asked to rank for the wine they just have bought how important were the following cues for the purchase decision, using a 7 points Likert scale, with 1 for the least important and 7 for the most important.
C1. The quality of the wine;
C2. The price of the wine;
C3. The fame of the wine;
C4. The availability of the wine;
C5. The COO of the wine is among the top wine producers;
C6. The COO of the wine is well known for its wines;
C7. The COO of the wine is among the top wine exporters.

A factor analysis using SPSS was made. The findings are as follows:
For IC, the top 3 correlations could be explained by the COO effect, specifically the correlations between C5 and C7(0.609), C7 and C4(0.487), C5 and C4(0.417). For RC, the top 3 correlations could be explained by the COO effect, specifically the correlations between C5 and C6(0.661), C5 and C7(0.584), C6 and C7(0.579). The KMO coefficient is 0.688 for IC and 0.601 for RC, both of them with Sig=0.000.

For IC, four principal components were identified, explaining 67.493% of the total variance. The first component includes the initial variables C7(0.848), C5(0.798), C4(0.700), C1(0.632) and explains 35.38% of the variance. The second component includes just C2(0.838) and explains 16,83% and the third component includes just C6(0.916) and explains 15.29%.

For RC, three principal components were identified, explaining 64.28% of the total variance. The first component includes C5(0.815), C4(0.795), C7(0.780), C6(0.760), C3(0.633) and C1(0.628) and explains 47.43%. The second component includes just C2(0.965) and explains 16.85%.

Table 4: The means for purchase decision

	The means for	
The cues	IC	RC
The quality of the wine	5.941176	5.692308
The price of the wine.	5.098039	4.403846
The fame of the wine	4.764706	4.480769
The availability of the wine	4.196078	4.865385
The COO of the wine is among the top wine producers	4.28	4.423077
The COO of the wine is well known for its wines.	4.490196	4.596154
The COO of the wine is among the top wine exporters	5.215686	3.942308

Table 4 allows us to see the main similarities and differences between IC and RC. Similarities: both IC and RC considered the quality of the wine as the main cue in purchase decision and the fame of the wine stands on the fourth place. Differences shows an interesting symmetry, for instance, the availability stands on the second place for RC and on the last place for IC, COO is well known for its wines stands on the second place for IC and on the last place for RC. Price stands on the third place for IC and only on sixth place for RC. For RC is important that COO is among the top wine exporters(third place), yet only on the fifth place for IC. COO is among the top wine producers stand on the fifth place for RC and on the sixth place for IC.

ANOVA was used to analyze the influences of age, gender or income on purchase decision(C1-C7) for IC and RC. The findings showed that gender have no influence on purchase decision for IC and for RC, due to the fact that Sig>0.05, therefore the null hypothesis cannot be rejected. The age of RC influenced

the purchase decision only on two variables: C4-The availability of the wine(Sig=0.000) and C6-The COO of the wine is well known for its wines(Sig=0.026). For IC, the age influenced only C1-The quality of the wine(Sig=0.033). The same variable C1 is influenced by income(Sig=0.045) for IC and for RC the income have no influence on purchase decision.

V. Conclusions

For consumers' opinion, the averages for COO cues are slightly smaller than the wine cues for IC and for RC, meaning the cues regarding the wine are more important compared to the cues regarding COO or ROO. The top 3 countries for all cues in consumers' opinions are the same as the top 3 countries in the opinions of the Masters of wine, namely France, Italy, Spain. All three countries are perceived as countries with great tradition and well known for wine, top wine producers and wine exporters, main players in the wine market.

In the opinion of Romanian winemakers and of the Masters of wine, the first factor "COO and the wine quality" explains 17.04% for Masters of wine and 19.08% for the Romanian winemakers of the total variance, emphasizing a strong correlation between the COO and the perceived quality of the wine, that is consistent with the consumers' opinions.

For purchase decision, what mattered most was the quality of the wine for IC, as well as for RC. Now, how could a consumer know the quality of the wine at the purchase point? Of course, if the consumer has expertise on wine, won't be too difficult to process the information on label and take a rational decision. But it was not the case for IC or RC, because only 15.68%, respectively 13.46%, bought wine on a regular basis and their personal opinion weights more than other people recommendation on buying intention. Therefore, at purchase point, an average consumers decide the wine meet his/hers quality expectations based on information written on the label. Along with price, COO/ROO are strong predictors for quality. Again, the averages for COO cues are higher than for wine cues, 4.98 compared to 4.68 for IC and 4.66 compared to 4.58 for RC, a unlike for consumers' opinions. Therefore, hypothesis H1, H2 and H5 are supported. H3 is partially supported only for IC. Hypothesis H4 is rejected and we can conclude that the reputation of the COO did not depend on the price of the wine for both IC and RC and might be explained by the reputation of the wine for IC and by the reputation of the brand of the wine for RC.

Exploring the Strategic Alignment Concern When Switching Toward Cloud ERP

Karim Mezghani, Assistant Professor, Al Imam Mohammad Ibn Saud Islamic University (IMSIU),

Riyadh – Kingdom of Saudi Arabia, mezghani_karim@yahoo.com

Abstract:

Since the development of the Strategic Alignment model (SAM) by Henderson and Venkatraman, the IT-business alignment emerged as an important issue when evaluating the IT projects success and involved several studies showing the necessity of such alignment. When talking about enterprise systems, mainly the ERP (Enterprise Resource Planning), alignment was shown as a critical factor for ERP projects success. The development of cloud computing and the difficulties linked to on-premise solutions implementation are pushing many firms to switch toward cloud-based ERP. However, existing studies on such systems adoption focus basically on benefits and risks issues. Thus, this paper aims to explore the alignment concern when switching toward cloud ERP. Through a literature review, the author first presents the alignment concerns during IT implementation and the factors that could help to achieve alignment. Then, by reviewing the existing studies on cloud ERP in terms of benefits and risks, the alignment concerns linked to such solutions are identified. From this literature review and then a case study conducted within a Tunisian firm, it is showed that cloud ERP alignment is a challenging issue that should involve adaptations (technical dimension) and social practices (social dimension) to be achieved.

Key words: Cloud ERP, alignment, switching, social dimension.

1 Introduction

Since the 90's, many firms (large and small) began to largely adopt the ERP (Enterprise Resources Planning) systems as software packages that can be used to manage all business processes. Besides being connected to a single database, these systems are developed based on “management best practices”. Despite these benefits, implementing or updating an ERP remains difficult and expensive since it involves big changes in technical and business infrastructures.

One of the concerns linked to ERP implementation is alignment. Indeed, ERP systems affect almost all business processes and even some strategic choices of a firm. That is why many researches focus on alignment concerns when studying ERP implementation (Hong and Kim, 2002; Yaseen, 2009; Mezghani and Mezghani, 2014). Nevertheless, with the development of cloud computing, firms are more and more interested in switching toward cloud ERP (Mezghani, 2014). Thus, "their business strategy, IT strategy, business processes and information technologies shall be re-aligned […] These bring great challenges for business–IT alignment of an enterprise in the cloud computing environment" (Li et al., 2011). ". Also, with cloud ERP, data and applications are provider-hosted. So, the way ERP is managed may be redefined and, then, achieving alignment might be different.

Thus, this paper aims to explore the alignment challenge when firms decide to switch toward cloud-based ERP. To do this, the author begins by a literature review to expose the alignment concerns linked to cloud ERP. The theoretical ideas are then contextualized through a case study conducted within a Tunisian firm in two phases ((1) when implementing on-premise ERP, (2) when thinking to switch toward cloud ERP).

1 Literature Review

1.1 IT implementation and strategic alignment

Since the development of the Strategic Alignment Model (SAM) by Henderson and Venkatraman (1993), many studies were conducted to demonstrate the importance of aligning IT implementation with business strategy to gain greater benefits from IT investments. Indeed, according to these authors, the benefits of an IT are marginal if it is introduced without rethinking the existing organization and strategy. Croteau et al. (2001) add that companies that do not harmonize their strategic choices with their technology ones do not benefit from IT contributions to performance.

The importance of considering strategic alignment in IT implementation can be seen when analyzing the numerous studies on such subject, mainly those focusing on identifying the determinants of such alignment (Reich and Benbasat, 2000; Kearns and Sabherwal, 2007; Chao and Chandra, 2012; Mezghani and Mezghani, 2014).

From a literature review, one can note that the main enablers of strategic alignment are closely linked to social and managerial aspects rather than to technical ones. In fact, it is recognized that IT implementation needs technical adaptations to fit the business requirements. However, such adaptations are useless in absence of social interactions between IT specialists and business managers (Mezghani and Mezghani, 2014). Indeed, from the alignment duality perspective developed by Reich and Benbasat (2000), many empirical studies showed that the social dimension (communication, support, involvement,…) is the main factor that creates mutual understanding necessary to keep harmony between IT implementation and business (Schlosser et al., 2015). Moreover, as business and technology choices are continually changing, achieving alignment is considered as a dynamic matter that requires constant interactions between IT specialists and business managers.

Thus, alignment remains an organizational concern that frequently needs "to be addressed if optimal organizational performance is to be achieved" (Renaud et al., 2016).

1.2 Strategic alignment in a cloud computing environment

One of the most important changes noted in IT world last years is the emergence of the computing as a service called cloud computing. According to Mezghani and Ayadi (2016), the adoption of cloud computing involves changing the way to deploy IT within firms. So, "their business strategy, IT strategy, business processes and information technologies shall be re-aligned" (Li al., 2011). Indeed, in a cloud computing environment, misalignments can lead to decreased operating efficiency and losses for organizations (Géczy et al., 2012). However, "no cloud computing service vendor can satisfy the complete functional information system requirements of an enterprise" (Li al., 2011). These authors add that "sometimes, enterprises have to simultaneously use software services distributed in different clouds in conjunction with their intra-IS. These bring great challenges for business–IT alignment of an enterprise in the cloud computing environment". Katsanos (2014) adds that "using a mix of cloud providers may reduce costs, increase benefits and add more flexibility, but this can also create integration issues as well as complicate the enforcement of company security policies and practices".

From previous ideas, it clearly appears that achieving alignment is a real challenge in a cloud computing environment. Such challenge might be greater when a firm adopts an IT that requires much alignment efforts (adaptation, integration,…). It is noted that ERP, as standardized software packages, are largely considered as systems that needs such efforts. Thus, in a cloud environment, achieving alignment when thinking to switch toward a cloud-based ERP would be a more challenging issue. This will be discussed below.

2 Switching Toward Cloud ERP: The Alignment Concern

2.1 Cloud ERP: benefits and risks

Compared to on-premises ERP, cloud ERP propose a set of benefits that make it interesting to change toward such systems. Nevertheless, as cloud-based solutions, they involve some risks that may make

managers hesitant to adopt them. From previous studies comparing cloud ERP to on-premises ERP, Mezghani (2014) presented the main benefits and risks linked to cloud ERP implementation (table 1).

Table 1: Benefits and Risks of Cloud ERP

Cloud ERP benefits	Cloud ERP risks
• **Cloud ERP is cost saver:** moving to cloud ERP reduces costs linked to licensing, maintenance and upgrading (Makkar and Meenakshi, 2012). • **Cloud ERP is time saver:** less time is spent in monitoring IT infrastructure. Besides, tests and trainings are conducted from the first steps of the project which can help to save time (Elragal and Elkommos, 2012). • **High scalability:** according to Arnesen (2013), "you can add or reduce users as your needs change, which works especially well for seasonal businesses or companies on a high-growth path". • **Accessibility:** "as a cloud based solution, cloud ERP modules can be accessed anytime and anywhere through Internet" (Mezghani, 2014).	• **Security:** regarding cloud-based solutions, many managers perceive that the confidentiality and security of business data are not guaranteed (Benlian and Hess, 2011). • **Internet connectivity:** "If you lose connectivity because of a natural disaster or cyber-attack or if the vendor goes out of business, you may have no access to the system or data" (Arnesen, 2013). • **Dependency:** "even if choosing on-premises ERP, firms risk to become dependent on vendors since such systems need regular maintenances and updates. This dependency seems to be greater with cloud based ERP" (Mezghani, 2014). Indeed, according to Arnesen (2013), cloud ERP vendors retain the data and firms have to pay vendors on time or they may lose data access.

Regarding the benefits and risks associated with cloud ERP adoption, it seems that concerns linked to alignment should be considered when to switch toward such systems.

2.2 Cloud ERP alignment: a challenging issue

Linking cloud computing to IT-business alignment is an emerging matter that did not yet involve many studies. Nevertheless, when analyzing the existing ones, it is clear that cloud adoption needs to be accompanied by thoughts about strategic alignment. Indeed, "cloud computing as a new technology is involved in IT strategy. When planning IT implementation, the managers of an enterprise take cloud service as another resource apart from intra-IS. Intuitively, it enlarges the technological scope and extends the scope of IT governance. With high efficiency and flexibility, it also enhances the system competencies" (Li et al., 2011). These authors add that, from a SAM perspective, this change would have impacts on business strategy as well as business processes. According to Géczy et al. (2012), "it is important to align the organization's functional and operating model with the cloud-based model of utilization of information technology resources and services. Misalignments lead to decreased operating efficiency and losses for organizations".

Thus, in order to gain benefits from cloud-based solutions (as cloud ERP), it is necessary to manage the adoption of such solutions at the strategic and organizational level. When cloud ERP is an "enterprise system", the challenge of alignment is greater. Indeed, cloud ERP should normally satisfy all business requirements. "Without possibilities of customization, users and organizations may encounter substantial re-training and adjustment costs" (Géczy et al., 2012). However, as customers neither own the infrastructure nor run the applications, cloud ERP may fail to give customer greater sense of ownership to make the required changes (Salleh et al., 2012). Besides, cloud service provider has its general operational processes that could be adopted in most cases and provided to as many subscribers as possible but would not fit all individual requirements (Li et al., 2011). Arnesen (2013) adds that "Though configuration of cloud ERP is available to all customers, major customizations usually aren't allowed so the vendor can maintain the upgrade path". According to Peng (2015), "an

integrated solution from one single ERP vendor may often not satisfy all business needs of companies… different cloud vendors may use very different technologies and platforms to deploy and host their ERP packages. From a technical perspective, cloud vendors may not be able or willing to customize their ERP system to allow seamless integration between the package and other cloud or on-premise applications". Thus, it is difficult to customize a cloud ERP mainly when its components are purchased from various providers. Moreover, it is difficult to change cloud vendors even in the case of dissatisfaction (Dutta et al., 2013).

If firms opt for adapting their own processes, this involves alignment to an external unit (provider) that does not actively cooperate. Using a mix of cloud providers may also hinder alignment efforts as it can "create integration issues as well as complicate the enforcement of company security policies and practices" (Katsanos, 2014). Also, processes adaptations may require users training to the new practices. Dutta et al. (2013) note here that inadequate users' training on cloud services and usage could lead to resistance to technical and organizational changes. Thus, cloud-based solutions alignment is "more complex than that of past cases" (Li et al., 2011).

2.3 Social and technical dimensions as enablers of cloud ERP alignment

When analyzing previous studies focusing on alignment concerns in cloud computing adoption, one can note an emphasis on the technical dimension. Géczy et al. (2012) insist on the necessity of integration with the existing IT architecture, of customization at several levels to meet the changing demands of users and organization and of the network availability. Li et al. (2011) propose a structured approach that involves mapping the processes in order to identify what they call "collaboration points" to facilitate integration of business processes into the cloud. Although these adaptations may be rapidly run when adopting a cloud-based ERP, users' acceptance of such changes is not guaranteed (Salleh et al., 2012). Also, firms, especially small ones, would not have enough bargaining power to let the cloud providers customize the processes to meet one’s specific requirements (Li et al., 2011).

Thus, focusing only on technical aspects would be insufficient to meet the alignment requirements of cloud ERP. Such matter has been revealed with on-premises ERP projects and previous studies demonstrated the importance of the social dimension in these projects. That is why, considering this dimension when to adopt cloud-based ERP could be a facilitator factor mainly when it is known that alignment of cloud ERP is more complex. Based on the social dimension components and a review of previous studies focusing on cloud ERP, it is possible to present the contribution of the social dimension on cloud ERP alignment as follows:

- Top management support: According to Mezghani (2014), top management support is a key determinant of cloud ERP adoption. By prioritization of cloud adoption, IT managers could more effectively decide where and when to allocate financial resources for the implementation, deployment and maintenance of their complex IT systems (Chebrolu, 2011). From a social perspective, prioritization of cloud ERP adoption means that such adoption is considered at the strategic level (strategic fit). In fact, given the security concerns linked to cloud computing and the possibility to integrate modules from multiple providers, cloud ERP adoption needs to be managed strategically. From an operational level, prioritization means that top management allocates the required resources for customization and organizational change. As on-premises ERP, cloud ERP adoption needs such adaptations which would be facilitated when top management provides the required resources.
- Communication: According to Katsanos (2014), business and IT managers need to collaborate and communicate when to take decisions about cloud adoption (providers choice, security issues,…). As for on-premises ones, cloud ERP implementation requires software customization and organizational changes which needs frequent communication to identify the adaptation possibilities. Besides, adoption of a cloud ERP involves a third party (the provider) who will be in charge of deployment. However, this provider would not accept to make all required customizations (Li et al., 2011). Thus, communication could be a key factor to favor mutual understanding between managers and the provider and to help them identify the alignment possibilities.
- Users' involvement: As for on-premises ERP, cloud ERP adoption involves technological and organizational changes. So, users should be involved, even before choosing the cloud system,

to well identify requirements. If not, extra work would be done during the project and additional costs would be generated to satisfy the requirements. Then, cloud ERP would lose one of its benefits as cost saver. Involvement would be also beneficial for reducing resistances due to the changes of the used technology and business processes. When studying cloud ERP project steps, Makkar and Meenakshi (2012) find that involving end users is the second step and precedes the project team creation. This shows the importance of users' involvement to identify the organizational requirements.

- Training: When to switch toward a new IT, users need to be trained to use it effectively. The importance of training arises when it is about switching toward cloud computing, mainly cloud ERP, due to its limited possibilities of customization. Indeed, according to Géczy et al. (2012), unless customizable, a cloud-based system would require substantial organizational adaptations that involve users re-training to align to new practices.
- Interpersonal skills: Switching toward cloud computing involves changes in the required skills for managers since IT would be deployed by the cloud providers (Lequeux, 2009). So, managers would focus more on business issues of cloud-based solutions rather than technical ones. Then, managers would require less IT skills and more managerial ones. Regarding alignment concerns, as it is already noted, providers would achieve the customizations at a certain limit and that is why managers need to communicate and negotiate frequently with these providers. Having a set of interpersonal skills lets managers be better communicator and more convincing (Mezghani et Mezghani, 2014). Such skills are also useful for change management since successful changes require social practices (users' involvement, top management support,…) (Mezghani et Mezghani, 2007).

3 Research Methodology: A Case Study

Due to the exploratory nature of this research, the author opts for a qualitative approach based on a case study conducted within a Tunisian firm (PRO) specialized in producing and marketing IT goods. According to Yin (1994), the case study may be the most appropriate research method to study a complex organizational phenomenon. IT-business alignment involves many organizational changes that may be difficult to elucidate.

To provide a practical view of the theoretical ideas developed regarding cloud ERP in terms of alignment concerns, a comparative approach through a single-case study is adopted. According to Siggelkow (2007), "a single case can be a very powerful example". In fact, a previous research was conducted within this firm to study alignment during the on-premise ERP implementation. During this research, direct observation during 4 months and semi-structured interviews were conducted with the IS manager and the key ERP users. The concerned ERP is a Microsoft solution (Navision). The implementation project began in 2003 and PRO uses the same ERP till now (with regular updates). Actually, this firm is thinking about the possibility to switch toward a cloud ERP. Thus, an additional interview was conducted with the IS manger (as key informant) to explore the alignment concerns if to switch. The data collected during this interview are classified according the main themes of this research and analyzed manually.

4 Data Analysis and Discussion

To make comparisons between the on-premise ERP and the cloud one, the author begins by presenting the main results of observation and interviews linked to on-premise ERP implementation and alignment within PRO. The author focuses here on the sales process as the first process involved in the ERP project.

4.1 On-premise ERP implementation and alignment

When analyzing the business process and the ERP one before implementation, it is noted that the steps are almost the same. However, some misfit signs are detected when applying the process steps. The main signs are:

- A data entry operator is participating in the process. This is not conformed to the ERP process which predicted the removal of such operator to eliminate the double data entry.
- The goods codification is different (in terms of the characters' number allowed per code).

- The verification of the customers' outstanding amount before preparing their orders (this was not possible, *a priori*, with the ERP).
- When performing his tasks, the salesman uses the delivery orders as necessary documents. The ERP process predicted the removal of such documents.

Thus, the team project, in collaboration with top management, decided to make some adaptations within the ERP system and the business process. During the observation process, it is noted that these adaptations were necessary but not sufficient. Indeed, in the beginning, several adaptations were not concretized due to changes resistance and lack of clarity. The social dimension was then beneficial to achieve real alignment (table 2).

Table 2: Contributions of the Social Dimension to the On-Premise ERP Alignment[i]

ERP adaptations	**Contributions of the social dimension**
Basic configurations	• The project manager **communicates** frequently with the business managers to decide about adaptations. • Many users are **involved** to identify their needs. • The top manager **supports** users to identify clearly their needs.
Specific customization to be able to verify the customers' outstanding amount with the ERP system	• The project manager **communicates** frequently with the business managers to decide about adaptations. • Financial **support** from top management to achieve this additional adaptation.
Business process adaptations	**Contributions of the social dimension**
Converting the data entry operator function into a salesman function	• **Training** the concerned person to the new tasks. • Regular meetings (**communication**) with users to explain them the benefits of such change and track its achievement.
Creating a new codification	• Regular meetings (**communication**) with business managers to decide about the new codification. • Regular meetings (**communication**) with users to explain them the benefits of such change and tracking its achievement.
Removing the delivery orders use	• Regular meetings (**communication**) with business managers to decide about this process change. • **Training** the concerned person to the new method.

The conducted interviews revealed also that both IT and business managers demonstrated an important level of involvement in interactions and willingness in hearing and satisfying the users' needs. This shows that these managers have interpersonal skills which, in turns, helped them to accomplish their interpersonal roles as revealed in table 2.

In the following section, the author will explore if the IS manager is still willing to perform such practices when to switch toward a cloud ERP.

4.2 Switching toward cloud ERP and alignment concerns

As already mentioned, after studying on-premise ERP alignment within PRO, a semi-structured interview is conducted with the IS manager (who was the project manager when implementing the previous ERP) to explore the alignment concerns that could be linked to a cloud ERP implementation. Indeed, PRO is studying the possibility to switch toward a cloud-based solution.

The collected data are coded in reference to three main themes: intention to switch toward cloud ERP, alignment concerns and social dimension (table 3).

Table 3: Interview Results

Intention to switch toward cloud ERP	**Alignment concerns**	**Social dimension**
• IS manager intends to switch but he is actually studying risks and benefits with IT specialists and business managers within the firm. • Benefits: more flexibility for employees, no maintenance, no need to update. • Risks: compatibility, costs, security, connectivity, switching time required.	• "Switching must be **planned strategically**". IS manager affirms that such switching involves a double challenge: "cloud" and "ERP". • "Emergent technology in our context, we should also evaluate the cost efficacy regarding managers' needs". The IS manager insists on cloud ERP **customization** concerns in terms of costs. • IS manager thinks that having many existing applications is a challenge since switching would need **integration** with cloud ERP (technical fit). • IS manager prefers solutions that involve minimum **organizational change**.	• Frequent **discussions** with other managers within the firm to study the compatibility concerns and the eventual organizational challenges if to switch toward cloud ERP. • **Meetings** with cloud providers and IT specialists (outside the firm) to collect information about existing systems and the possibilities to provide offers according to the organizational needs. • IS manager thinks that **training** is an important matter when to switch because it would help users to be familiarized with any organizational change. • "Top management supports innovations". • IS manager thinks that, once provider is selected, regular **discussions** must be engaged to early plan the customizations.

From table 3, it is possible to note that the interviewed IS manager has the intention to switch toward cloud ERP but insists on the necessity to take the required time for evaluating the switching alternative in terms of benefits and risks. The IS manager discourse shows that, besides cloud-linked concerns (security, connectivity), thinking about switching toward cloud ERP integrates alignment concerns. Indeed, as cloud adoption involves big changes in the way the IS will be managed, the IS manager affirms that "switching must be planned strategically". Other alignment concerns can be noted from table 3 as cost efficacy of customizations, technical fits with some existing applications and the eventual organizational changes.

Another interesting result is the presence of the social dimension in the discourse of the IS manager. Indeed, although this manager focused mainly on technical aspects when talking about switching, his discourse integrates terms as "meetings", "discussions", "support" and "training" as practices to help doing customizations and switching.

4.3 Discussion and implications

Both the results from on-premise and cloud ERP studies within PRO show that alignment is a real challenge for ERP implementation. While alignment concerns linked to on-premise ERP were

empirically studied in several researches, the recent interview conducted with the IS manager of PRO can be discussed in reference to recent studies focusing on cloud ERP adoption. Even if "studies on cloud-based ERP are very limited" according to Peng (2015), these studies focus mainly on benefits and risks that can be linked to alignment concerns.

As reported in ERP literature, the ERP alignment can be reached by adaptations on the ERP system or on business processes. Such alternatives are mentioned within the IS manager discourse when talking about cloud ERP alignment:

- Cloud ERP adaptations concerns: the major concern, for the interviewed IS manager, is the cloud ERP customization. Indeed, during the actual period, PRO is collecting information about cloud ERP providers with a focus on the possibilities of customization and integration with other applications rather than on cloud-linked concerns as scalability or efficiency. First, this shows that the IS manager considers, as for on-premises ERP, the technical fit as an important matter when to choose and adopt a cloud-based ERP. Second, this shows that the IS manager is conscious that this fit is difficult to achieve and costly. As mentioned in the literature review, this fit "becomes even more difficult to manage in the cloud environment" (Peng, 2015). So, IS managers should really focus on such concern when thinking about switching.
- Business processes adaptations concerns: if cloud ERP customization is difficult and costly, managers may opt for business processes adaptation. Although the interviewed IS manager does not prefer to do such adaptations, the fact that he mentioned such alternative shows an awareness of it. This reveals a reflection in term of processes alignment and illustrates the challenging issue of this alignment when to switch toward cloud ERP. Indeed, this alternative may cause change resistance. Moreover, Salleh et al. (2012) add that "in terms of organizational change, Cloud ES may fail to give customer greater sense of ownership as they neither own the infrastructure nor run the applications". Besides, when integrating applications from many providers, this involves alignment to many external units. This could be a risky choice that must be well studies before switching.

As during on-premise ERP, the interviewed IS manager is conscious about the alignment-linked risks when to switch toward cloud ERP and insists on the social dimension-linked practices to reduce such risks. Nevertheless, as reported in tables 2 and 3, one can note that while social dimension involves interactions mainly within the firm in the case of on-premise ERP adoption, this dimension is extended to involve external units when thinking about cloud ERP. Indeed, the IS manager insists on discussions and meetings with providers to study closely the customization possibilities. This is evident since cloud solution deployment is assumed by a third party.

To sum up, alignment appears as a real concern even when talking about cloud ERP presented theoretically as an alternative to on-premise ERP that can be adopted quickly and with less concerns. Moreover, it is a true challenge since all kinds of adaptations would be monitored with a third party. From the literature review and the interview results, the social dimension components could be presented as supportive practices to well achieve alignment when reducing risks.

Based on these ideas, a preliminary framework is proposed (figure 1). This framework can be useful to clarify the alignment challenge when to switch toward cloud ERP. Such framework needs to be discussed deeply through additional case studies.

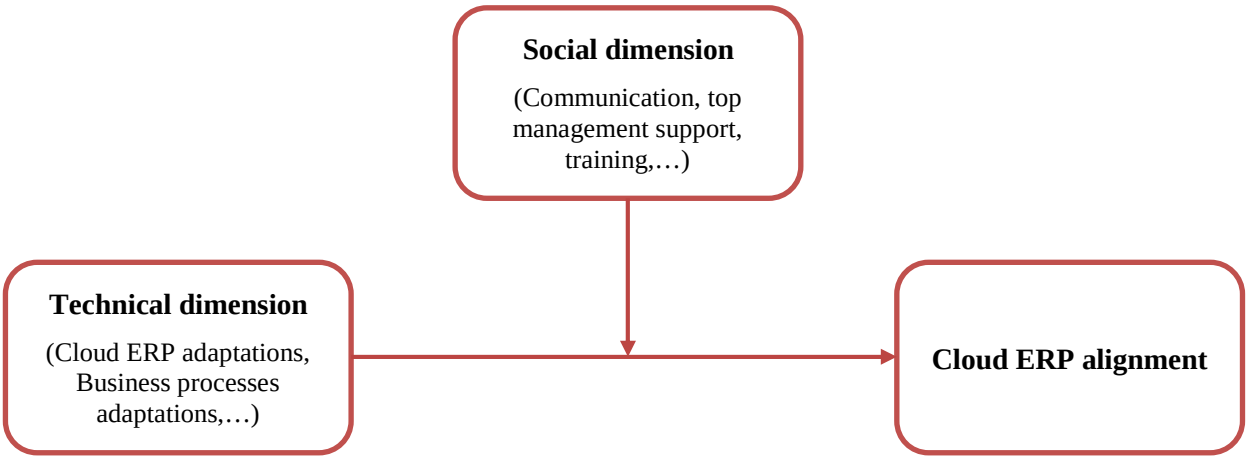

Fig 1: Framework for Alignment Challenge

5 Conclusion

This paper aims to explore the alignment concerns linked to cloud ERP adoption. In fact, since the development of the SAM by Henderson and Venkatraman (1993), it is argued that IT-business alignment is a significant sign of IT projects success. Besides, this concept involved several researches in IT field. When analyzing the evolution of these researches, Parappallil et al. (2012) affirm that there is an on-going trend toward studies focusing on alignment concerns linked to cloud computing due to "the enormous increase in IT outsourcing and investments in Cloud Computing services".

Even the evolution of cloud-based ERP as an alternative to on-premise ERP, "studies on cloud-based ERP are very limited" (Peng, 2015). The existing ones focus mainly on describing benefits and risks without reflection to alignment concerns although such concerns were presented as key factors for on-premise solutions success.

Through a literature review, the author tried to identify the alignment concerns linked to such solutions. It is stated that these concerns are a true challenge since a third party (providers) is closely involved in cloud ERP implementation and deployment. Indeed, as an ERP, cloud one would require system and processes adaptations. However, these adaptations seem more risky since they involve external actors that can be more than one provider (cloud ERP applications can be bought from many providers).

These ideas were supported by a case study conducted within a Tunisian firm in which a previous research focusing on alignment concerns during an on-premise ERP project was conducted. In fact, as for this project, the interviewed IS manager insists on the necessity and difficulty of achieving alignment if to switch toward cloud ERP. The results of this case study join the theoretical statements through which the technical dimension is important to make the required adaptations to reach alignment. However, this dimension may be insufficient to reduce risks linked to adaptations and need to be supported by social practices. Indeed, as for on-premise ERP, potential failure of cloud ERP should be attributed to human problems (Peng, 2015).

From these ideas, a framework is proposed (figure 1). This could be helpful to conduct further research on alignment challenge linked to cloud ERP. This framework needs to be discussed deeply through additional case studies.

From a managerial perspective, this research could help firms thinking to switch toward cloud ERP as the used case study shows empirically some of the alignment concerns and the required practices to overcome them.

Abstract

As many public sector organisations are facing funding cuts, the prominent contributions of NPOs in providing sustainable public services is growing as without these efforts, communities will collapse with devastating effect on the country's development. However, it is vital for NPOs to provide sufficient transparency level through their annual report to facilitate the assessment on their accountability due to the increased public scrutiny regarding the manner in which NPOs are run and managed as there are increasing incidences of fraud and misappropriation of assets by NPOs. Hence, this study examines the extent of disclosure made by the NPOs in relation to financial reporting, anti-money laundering and terrorism financing perspective. The annual reports of 83 NPOs registered with Companies Commission of Malaysia were assessed for the year of 2009 until 2011. Findings of this study for the financial reporting perspective revealed that, the disclosure of NPOs is only at moderate level towards the financial stability, whereas, disclosures for the financial performance and organization efficiency was relatively weak. Similarly, results showed that the disclosures of anti-money laundering and terrorism financing within NPOs in Malaysia is weak. This in turn is expected to provide useful information in strengthening NPOs transparency level with the ultimate aim to increase their credibility to build the public trust.

Keywords: Non-profit organization, financial reporting, anti-money laundering, counter terrorism financing

Introduction

A non-profit organization (NPO) is also widely known as not-for-profit organization comprises of non-governmental organization (NGO) and charities (Connoly and Kelly, 2011). The importance of this NPO is broadly associated with the provision and assurance of reliable public services such as health and social services which are crucial for any commodities. To date, the crucial debate arises that focus on the transparency of NPO as according to FATF (2013), the non-profit sector is associated with money laundering and terrorism financing activities. Financial Action Task Force (FATF) was established in 1989 as a policy-making body that is responsible to generate political will in the development of legislative and political reforms in the areas covering anti-money laundering and terrorism financing. Therefore, it is crucial for NPO to have the quality and transparency in reporting (ICAA, 2013) to maintain, protect and enhance public trust and confidence.

Transparency would form a key element towards the NPO performance and sustainability due to their vital role in societal development. However, the frequently asked questions surrounded the transparency of NPO is to what extend NPO is said to be transparent enough and how to achieve that. As for Malaysia, the current reporting framework only requires compliance with minimum regulatory requirements which caused unsatisfactory impact on the level of transparency. Therefore, the regulatory authorities are engaging various efforts in order to promote transparency as one element of good governance practice for NPO in response to the Asia Pacific Group (APG) requirements as APG is responsible to assess the compliance with recommended practices by FATF in the Asia Pacific region.

Transparency at the same time has become the global phenomenon as enhancing transparency would provide accurate, complete and informative information to particularly regulatory authorities as well as relevant stakeholders in conducting effective supervision or monitoring and effective information gathering and investigation on the non-profit sector (FATF, 2013). However, NPO needs to identify several significant areas to focus on which would be parallel with their mission to mainly discharge the social activity which overrides any financial motive so that there would be a sustainable pipeline in order to meet the needs of diverse range of stakeholders which include investors, beneficiaries and the public itself so that they are able to be more self-sustaining. At one time, NPO might experience the challenge in reconciling this new demand. Nevertheless, increasing recognition of their role in discharging the public services and a better understanding of how this might be achieved is vital. This paper seeks to bring clarity on the magnitude of transparency in order for NPO to gain its sustainability and able to improve their performance to social at large through clarity of any inconsistencies and ambiguities right from the start.

The understanding of NPO and its role is vet through to clear the ambiguity of imprecise distinction between organizations as well as to give clearer notion of NPO. Then, this paper discusses on the transparency which focuses on the financial reporting perspective, anti-money laundering and counter terrorism financing. This is significant in determining the milestone currently the NPO has set in relation to their accountability and the factors that influenced such actions and this paper also explores the magnitude of transparency in relation to sustainability of NPO and its performance by taking into account the contextual factors in which the NPO operates.

Understanding the NPO and its Role

NPOs fall under the third sector which is also known as charitable sector, voluntary sector or social sector. According to Macedo and Pinho (2006), NPO is an association of individuals who perform public tasks that have been delegated by the state and perform public tasks for which there is demand that neither to be performed by the state nor for-profit organizations. NPOs also influence the direction of policy in the state, the for-profit sector or other NPOs. According to the International Classification of Non Profit Organizations (ICNPO), there are 12 categories of NPOs in the system, namely, culture and recreation; education and research; health; social services; environment; development and housing; law advocacy and politics; philanthropic intermediaries and volunteerism promotion; international activities; religion; business, professional associations and unions; and lastly those that are not elsewhere classified.

There are countless significant roles carried by NPOs which focus totally on society as NPOs are not interested in profit (Gonzalez, Vijande and Casielles, 2002). NPOs are becoming an important part of our society as it offers important services that are relevant for the society such as health, social welfare and education (Duque-Zuluaga and Schneider, 2006) as well as cultural, religious and public objectives (Bottiglieri, Kroleski and Conway, 2011) which are not provided by for-profit sector. According to Mokwa (1990), the main purpose of NPOs has been established as to organize and oversee voluntary social action to solve the humanitarian problems which embrace significant social ideas and perform critical social function such as attracting resources, for example, funds and volunteers, establishing priorities for social action program and allocating resources to beneficiaries. Moreover, Salamon (1999) argued that, NPOs are established in order to serve four critical functions, namely, providing programs and services to the community, providing a mechanism for promoting individual initiatives for the public good, providing means for drawing public attention to social issues and developing a sense of community among the citizens by providing means of engaging in social welfare.

Methodology

Sample and Data Collection

This study focuses on the 83 NPOs from various backgrounds that have registered the establishment with the Companies Commission of Malaysia. The research approach involves the content analysis of annual

reports which consist of the 3 years data under reviewed collected from year 2009 until 2011. Content analysis has been widely used in prior studies (e.g. O'Donovan, 2002; Clemens and Douglas, 2006) for the purpose of measuring voluntary and mandatory disclosures in annual reports. This study emphasis on the data disclosed in relation to the financial reporting perspective, anti-money laundering and counter terrorism financing.

A summary of the main categories of data disclosure is shown in Table 1 below.

Table 1: Main Categories of Data Disclosure

Category 1 Information on Financial Reporting Practices	**Disclosure Items**
	Financial Position/Stability (15 items)
	Performance of Financial Policies (5 items)
	Organisational Efficiency (3 items)
Category 2 Information on Anti-Money Laundering and Counter Terrorism Financing	**Disclosure Items**
	Board Committee, Policies and Strategies (9 items)
	Sources of Revenue (6 items)
	Fund Management (3 items)
Total number of items	**41 items**

A summary of the disclosure items under Category 1 of data disclosure are listed in Table 2.

Table 2: Summary of Disclosure Items under Category 1

Financial Position/Stability	
1	Statement of income (receipts) and expenditure (payments)
2	Statement of financial position
3	Statement of changes in equity
4	Cash flow statements
5	Revenue from principle activity
6	Details of revenue from principle activity
7	Other sources of revenue
8	Details of other sources of revenue
9	Other expenditure
10	Details of other expenditure
11	Commitments and contingencies
12	Accounting policies
13	Accounting treatment on provision of bad debts
14	Accounting treatment on current assets
15	Accounting treatment on assets and liabilities
Performance of Financial Policies	
1	Summary of management and performance policies
2	Explanation of reflection on performance during the period covered by trustee
3	Operating statement
4	Budget information and overhead allocation
5	Auditors opinion on financial performance of organisation
Organisational Efficiency	
1	Program spent
2	Fundraising method and expenses
3	Capital management statement

A summary of the disclosure items under Category 2 of data disclosure are listed in Table 3.

Table 3: Summary of Disclosure Items under Category 2

AML Committee, Policies and Strategies	
1	Anti-fraud policies strategies
2	Oversight board committees
3	Anti-money laundering (AML) training for members
4	List of directors
5	List of members
6	List of employees
7	List of volunteers
8	Statement of changes in circumstances
9	Statement of unusual nature item
Sources of Revenue	
1	Types of charities
2	Revenue from principal activities
3	Details of revenue from principal activities
4	Other sources of revenue
5	Details of other sources of revenue
6	Investment income - if any
Fund Management	
1	List of activities for generating funds
2	Details of fund distribution
3	Details of fund utilisation

It is important to understand the types of information reported as well as determine the extent of information being reported by NPOs in their annual reports. Therefore, this study investigates the extent of disclosure using the disclosure score as per Table 4 below.

Table 4: Disclosure Score for Data Disclosed

Financial Reporting Practices	
Score	**Indicators**
0	No disclosure
1	Briefly disclose, mainly descriptive and qualitative information
2	Disclose with quantitative and qualitative information
Anti-Money Laundering and Counter Terrorism Financing	
Score	**Indicators**
0	No coverage/No disclosure
1	Minimum coverage/Less detailed
2	Detailed and honest, including organisation's shortcomings and commitments

A content analysis of the data gathered was carried out using Statistical Package for Social Science (SPSS) software that resulted with various descriptive statistics covering the main categories of data disclosure.

Financial Reporting, Accountability and NPOs

Concern about the lack of transparency in NPO sector has been expressed by the donors and relevant stakeholders. Past literature highlighted the refusal of most NPOs to disclose information in their annual reports (e.g. Burger and Owens, 2010; Behn, DeVries and Lin, 2010). Financial reporting should be transparent in order to encourage trust within and of the NPOs and the external pressure for transparency

come in placed as it deals with public fund (Chartered Accountants of Canada, 2011) and works for the public benefit. NPOs need to combat on the common perspective of their financial reporting to be less trustworthy, less useful and less relevant. Therefore, the annual report represents the best way to demonstrate the extent of transparency that should meet the best practices by providing comprehensive disclosure on its achievements and future plans. According to Flack and Ryan (2002), annual report is a useful mechanism to provide sufficient transparency through the information disclosed for discharging accountability to the stakeholders as a whole. The proposal for increased financial reporting requirements was due to the increasing voices from the public to observe the accountability of NPOs (Calabrese, 2011). This in overall could increase the credibility of NPOs in the long run.

Financial Position / Stability

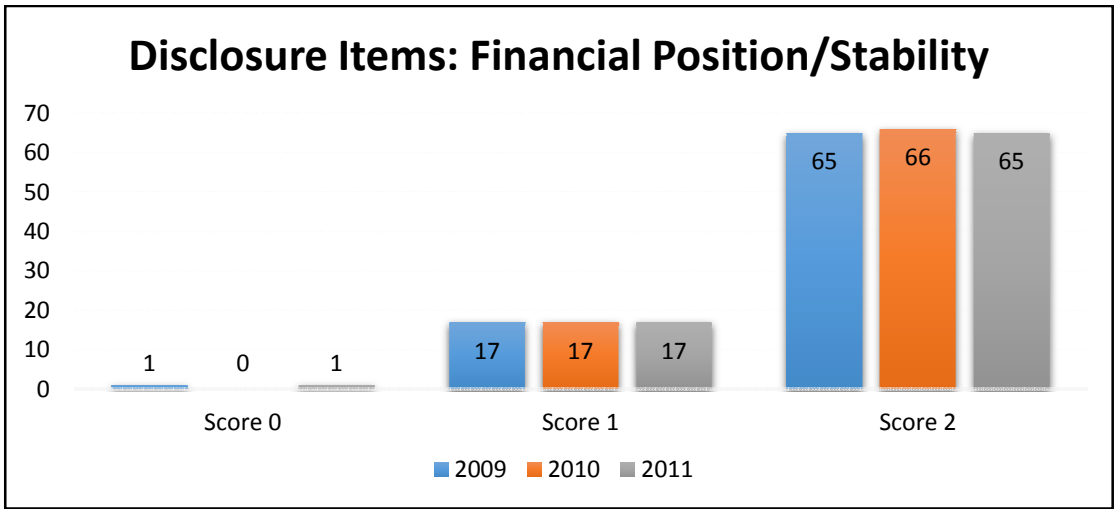

Figure 1: Financial Position/Stability Disclosures

The review of 83 NPOs' annual reports showed that 67% of the disclosure items under financial position/stability have been disclosed constantly by nearly half of NPOs throughout the three years under review, that is 37 NPOs in year 2009, 38 NPOs in year 2010 and 36 NPOs in year 2011. This is a good signal for NPOs to gain the public trust as most of the companies willing to demonstrate their transparency, in particular, to provide useful information in relation to financial position, sources of revenue received and expenditure incurred which could be the main focus by the stakeholders. It is an important strategy showed by NPOs in ensuring their stability in the long run by communicating relevant information on financial position to the current and future resource providers.

Furthermore, due to the current economic environment, many public sector organisations are facing funding cuts. Therefore, the prominent contributions of NPOs in providing sustainable public services is growing and it is paramount for the NPOs to record and provide details information on the sources of revenue received since NPOs rely on a mix of revenue sources such as donations, government grants, earned income and investment income which ultimately would be scrutinized by the public at large. Withdrawals of support by the donors and other stakeholders might happen in the situation where NPOs fail to communicate sufficient information regarding the effectiveness in managing the resources. This negative perception should be avoided as accountability increases credibility of the organisations (Gray and Bebbington, 2006) with consequent positive impact on organisational sustainability.

There is an important link between transparency and sustainability of NPOs as the provider of public services. The ability of NPOs to establish these relationships is expected to result in the flow of resources to the organisations. However, NPOs are still not taking full advantage of the financial statements as communication device to gain donors and public trust based on five best practices, namely, completeness,

accessibility, transparency, full disclosure and relevance (Gordon, Khumawala, Kraut and Neely, 2010). As a consequence, limited disclosure by NPOs due to the incomplete of record keeping, limited financial monitoring and unstructured volunteer management would hinder NPOs growth, sustainability and effectiveness (Minzner, Klerman, Markovitz and Fink, 2014).

Performance of Financial Policies

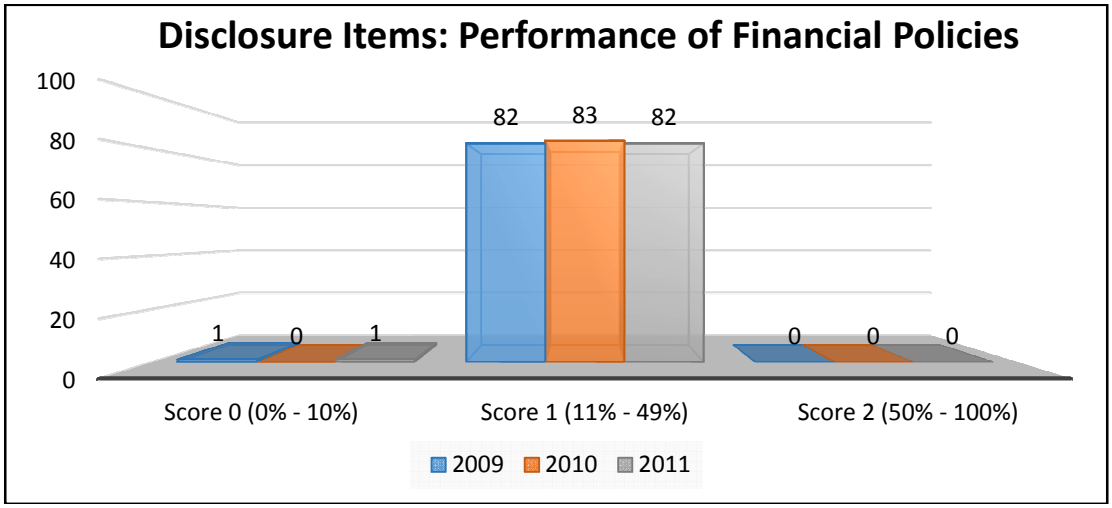

Figure 2: Performance of Financial Policies Disclosures

According to Gonzalez et al (2002), NPOs can be defined as the organisations without a financial objective, under private control which aims to generate a social benefit for a specific sector of society. The result gathered from the 83 NPOs showed that only 33% of the disclosure items under performance of financial policies have been disclosed by the NPOs. From the result obtained, it can be agreed with the judgment of Gonzalez et al (2002) as no comprehensive disclosure has been made in relation to the financial performance of the organisations which can be relied upon to contradict with the negative perception. Moreover, it is believed that NPOs tend to delay the disclosure due to unfavorable news (Reheul, Caneghem and Verbruggen, 2014) which ultimately might affect the donation decisions as publicly available information is used as a guidance tool (Lammers, 2003). This is supported by Breckell, Harrison and Robert (2011) whereby only 8% of charity under review provided impact information in relation to external reporting, while on the other hand, 68% provided some information on outcomes. However, only few disclosed targets, reported the failure, all of which this kind of important information would be helpful for stakeholders' judgment.

Accountability involves ensuring the various aim and expectations of stakeholders are met. Therefore, it justified the requirement to have the comprehensive disclosure on the financial performance as the outcome of accountability lies with transparency. The study done by Said, Mohamed, Mohd Sanusi, Syed Yusuf (2013) showed that good internal control system enhance transparency of the mosque which caused programs carried out by the mosque will be improved as a consequences of enhanced donor's confident to contribute more fund. Apart from that, any opinion on the improvement of the financial performance of NPOs is essential to be disclosed so that it is answerable to the stakeholder in order to prove on the ability of NPOs to retain a portion of annual income for the purpose of reinvestment and sustainability since their mission may not be driven by the profit motive (McDonald, 2007).

Organisational Efficiency

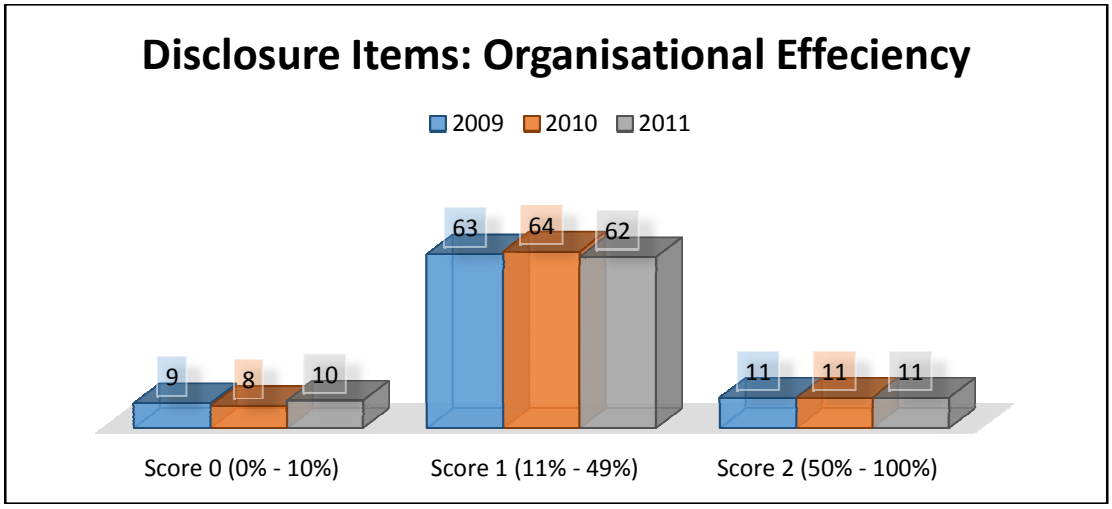

Figure 3: Organisational Efficiency Disclosures

It is paramount for NPOs to remain publicly accountable for very substantial public funds as their income would depend on mix sources such as public donations and government funding and fees. Therefore, the inflow and outflow of the public fund needs to be properly recorded and disclosed as individuals' belief that their contribution will be put to good use based on their trust (Taniguchi and Marshall, 2014). However, based on the reviewed data from the annual reports, the NPOs involved were only constantly disclosed 44% of the disclosure items under organisational efficiency. This shows that, there are still a lot of rooms for improvement need to be taken into consideration by NPOs to be more transparent in terms of their efficiency as they also face pressure from the external resource providers to present the evidence on how the resources are used and achievement acquired although they can voluntarily decide to measure on the social impact for their own purpose (Arvidson and Lyon, 2014).

The outcome of accountability is transparent as any actions must be answerable to the stakeholders. Therefore, the transparency should emphasis on the three areas which include, transparency on how funds are spent, transparency in the method of intervention and lastly, to conduct regular monitoring and evaluation involving the stakeholders or making the outcomes of these known to the stakeholders (McGann and Johnstone, 2006). Apart from that, NPOs should aware that the extent of disclosure made on the efficiency particularly on the spending of public fund would have a significant effect on donations (Marudas, 2004). In particular, NPOs would survive substantially from public funds if they can manage the flow of resources and reduces the uncertainty in their environment (Pfeffer and Salancik, 1978).

The availability of NPOs information regarding the operation is crucial for donation decisions among the current and future donors. This will justify the efforts and efficiency of usage since the decision of donors would be based on the type of activities and effectiveness of the activities conducted (Iwaarden, Wiele, Williams and Moxham, 2009) to suit the primary purpose of having NPOs in delivering the public services. Even though there is no clear measurement on how to assess the effectiveness of NPOs, the accessibility of information disclose can actually assist donors and relevant stakeholders on their decision on donations so long as NPOs are able to convey the efficiency and effectiveness of the operation directly to them (Parsons, 2007). Therefore, the comprehensive disclosure in the financial reporting would indeed support the decision making among the donors besides building and strengthening the public trust.

Anti-Money Laundering and Counter Terrorism Financing Reporting

NPOs are organizations established with specific social missions which rely heavily on the contributions from supporters. NPOs normally process and manage a large amount of fund from various sources. However, since NPOs operated under a less formal regulatory control compared to public listed companies, thus, tendency of NPOs fund to be misuse for money laundering and terrorism financing is high. Issues of non-profit sector being misused for money laundering and as terrorist entities have been a long held practice (Winer, 2008). For example, according to Bricknell, (2011) one of the NPOs known as Irish Republican Army (IRA) was doing fundraising for their paramilitary activities. Besides, there is also known exploitation of charitable giving by some groups such as Hamas and Hezbollah. Due to the terrorist attack of 11 September 2001, NPOs were identified as potentially significant contributors towards terrorism financing, thus, have been included in Financial Action Task Force series in combating the issue. FATF has given some serious recommendations to increase the transparency of NPOs. Among of them are to adopt methods of best practice with respect to financial accounting, verification of program specifics as well as development and documentation of administrative (FATF, 2013). Thus, a comprehensive disclosure among NPO sector is required to ensure NPOs are not being misused for money laundering and terrorism financing.

AML Board Committees, Policies and Strategies

Special Recommendation by FATF advises countries to review their laws and regulations to protect the NPO sector from being misused by terrorist organizations posing as legitimate entities. The establishment of board committee to develop policies and strategies regarding money laundering and terrorism financing is crucial to ensure charities are capable in dealing with this complex and specialized issue. Besides, it also helps in building community trust and demonstrates charities responsiveness towards anti money laundering and counter terrorism financing. According to UK Corporate Governance Code, the board committee should be represented by members that have appropriate and sufficient skills, experience, independence and knowledge in order for them to discharge their duties and responsibilities. Thus, the appointment of board committees is crucial in managing anti-money laundering and terrorism financing. Besides, oversights boards can also be one of the options for the charities in oversee the issues.

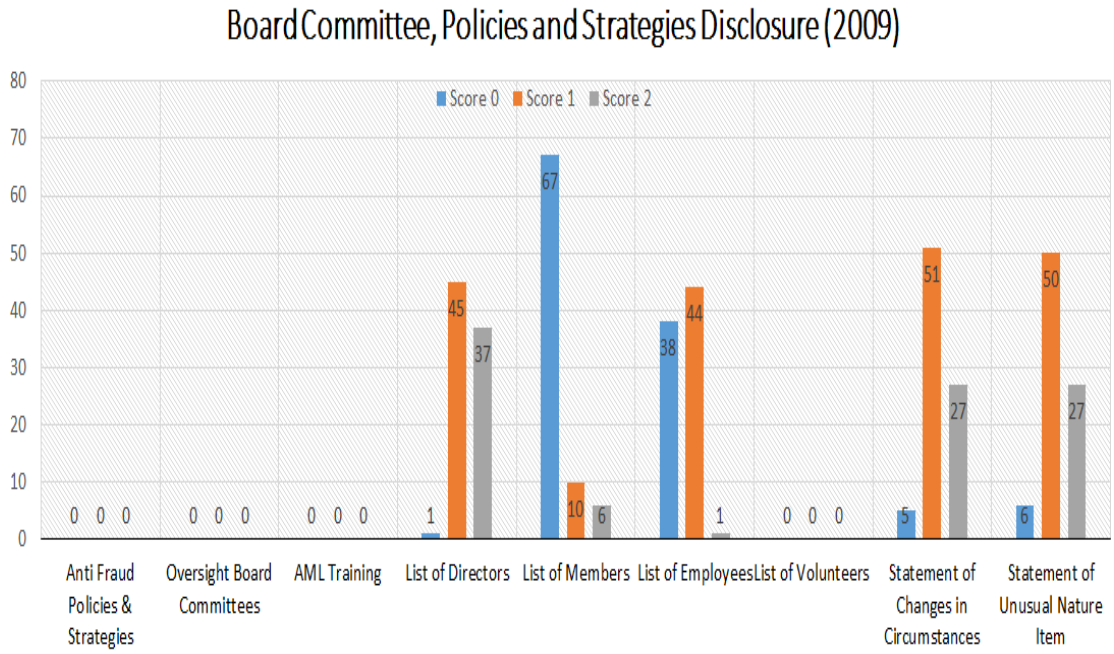

Figure 4: Board Committee, Policies and Strategies Disclosure (2009)

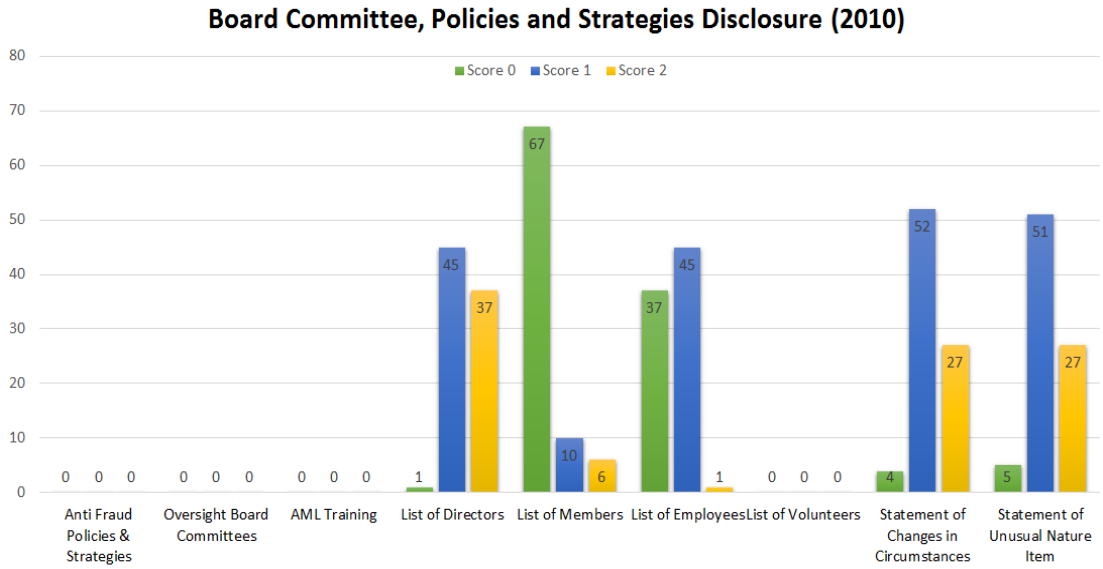

Figure 5: Board Committee, Policies and Strategies Disclosure (2010)

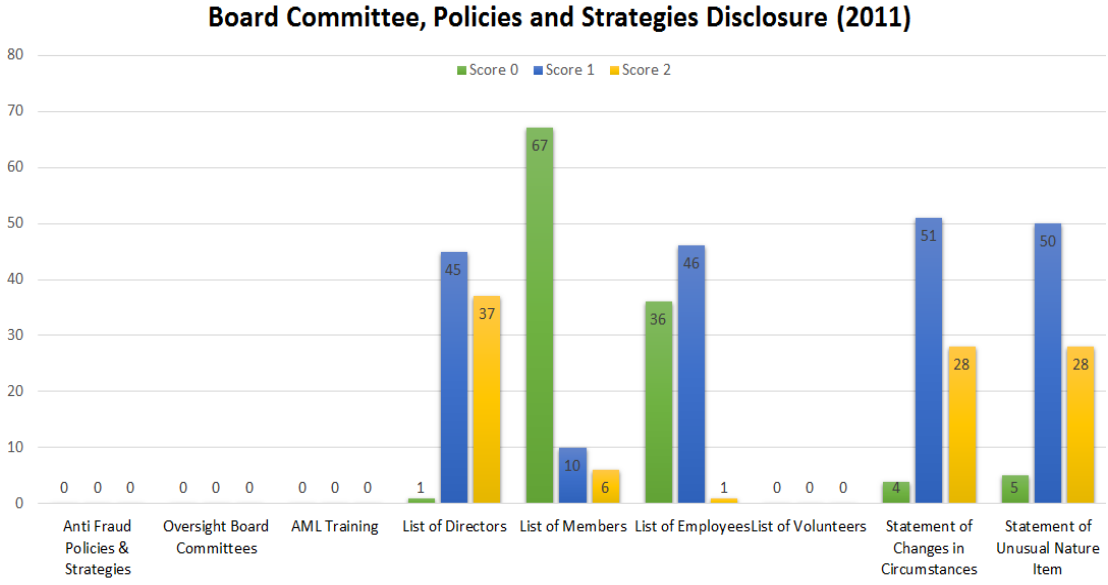

Figure 6: Board Committee, Policies and Strategies Disclosure (2011)

From the analysis run throughout the three years (2009-2011), it is found that none of the charities in Malaysia discloses information regarding the board committee, policies and strategies in combating money laundering and terrorism financing. Besides, there is also no information regarding sending the charities members to be involved in anti-money laundering courses and training. The results might indicate that, out of all the 83 charities, none of them has established Anti-Money Laundering board committee and has not started to initiate information on anti-fraud policies and strategies. We might also say that NPO sector in Malaysia is not responsive enough and lacks of awareness towards these issues, which lead to NPOs in having high potential to be misused for money laundering and terrorism financing. However, if the charities have undertaken the establishment of board committee, policies, strategies and

ongoing training of anti-money laundering and terrorism financing, good governance requires those to be disclosed in the charities annual reports.

In addition to the disclosures of board committee, charities in the first place should emphasize on the list of directors, members, employees and volunteers. However, from the analysis conducted throughout the 3 years, none of the charities disclose information on volunteers involved in their activities and only 20% (16) charities disclose information on members of the charities. Besides, more than 50% (42) of the charities disclosed the minimum disclosures about their employees. From the analysis, it is found that most of the charities, 99% (82) disclosed information on their directors. However, only 45% (37) of charities explained in detail and uses director biographies to demonstrate skills, experience and diversity of board of directors. Out of 83 charities, about 6 of them did not disclose any information in the statement of changes in circumstances and unusual nature. In addition, 34% (28) of the charities explain detailed information on changes of circumstances and unusual nature.

The charities in Malaysia are encouraged to disclose information on the AML board committee members by giving brief biographies of the board trustees so that users can understand the range of skills and the diversity of the trustees. Policies and strategies on anti-money laundering and terrorism financing should exist and the disclosures should be in detailed sentences including how often the policy is reviewed. This is in accordance to Statement of Recommended Practices (SORP, 2013) which highlighted that good reporting is when the charities provides a coherent explanation of the charity's policies and strategies, also explaining the activities undertaken to combat money laundering and terrorism financing.

Sources of Revenue

In response to the dynamic environment, NPOs become more financially concerned towards attracting revenues to help them succeed in delivering their mission-related activities. Jiao (2011) has reported that NPOs have been found to be involved in business professional operations or having other trading income as a backup to serve the community better. Thus, disclosures of revenue in the charities annual reports are crucial since there is a diversification in their revenue sources. In the case of money laundering and terrorism financing, disclosures of revenue sources helps to provide information on where the money comes from and how the money are being used.

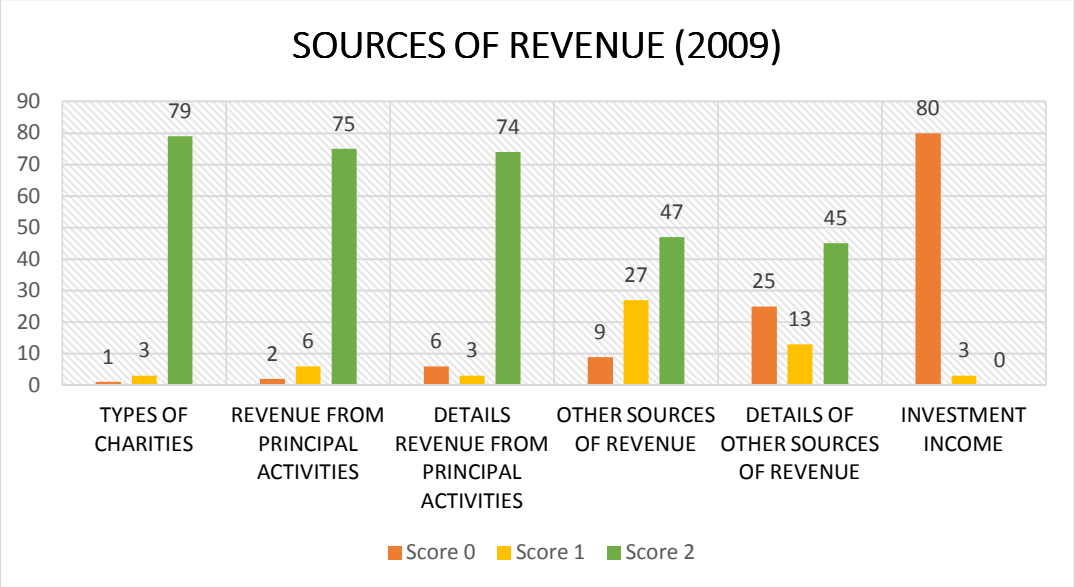

Figure 7: Sources of Revenue Disclosure (2009)

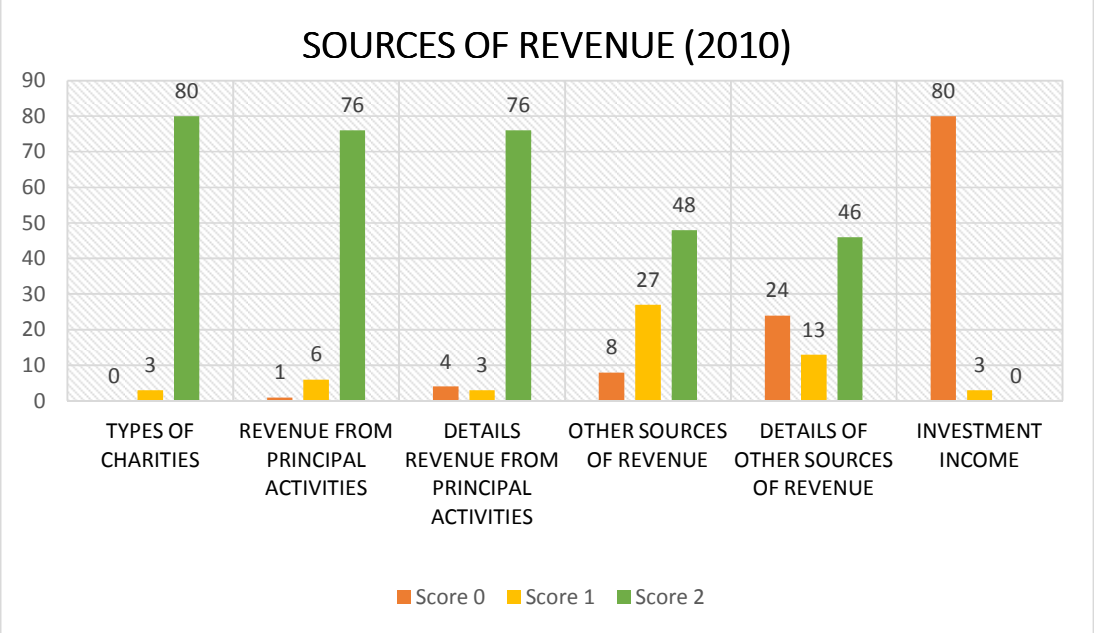

Figure 8: Sources of Revenue Disclosure (2010)

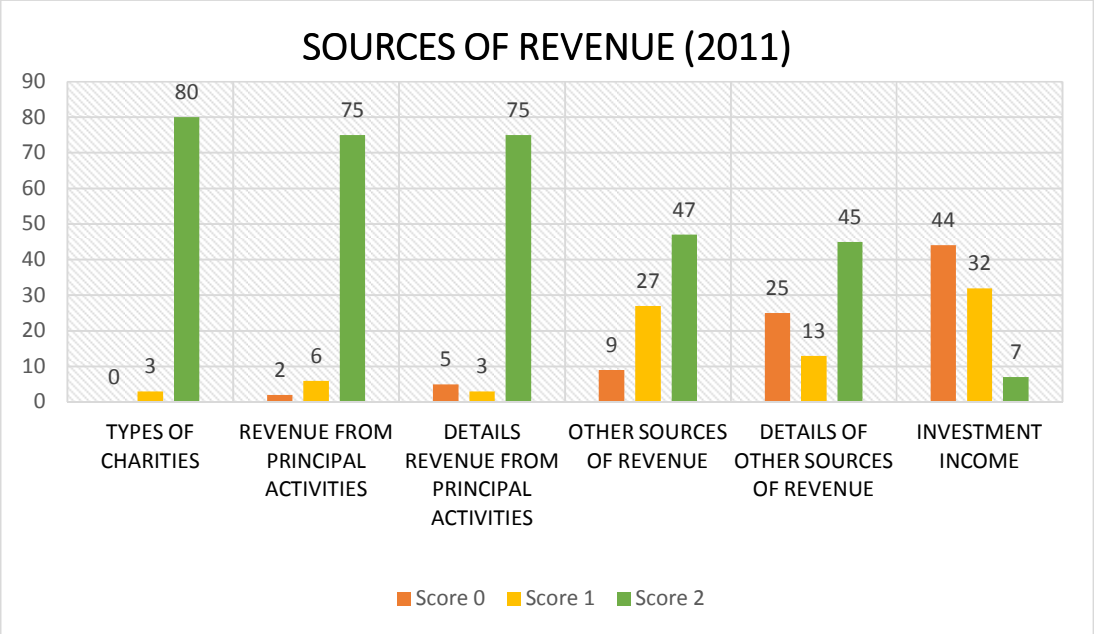

Figure 9: Sources of Revenue Disclosure (2011)

From the analysis, 96% of NPOs disclose in details the type and nature of charities; also details of revenue from their principal activity which are mainly from membership fees, grants and donation. However, information on the other sources of revenue such as investment income and business generation income are not disclosed even with a brief explanation except for the year 2011 whereby 7 out of 83 charities started to provide information on investment income such as rental, dividend and bonuses. This suggests that for year 2009 and 2010, all charities are highly dependent on their principal activities. On

the other hand, starting from year 2011, some charities have started to generate their own income through investment and business activities. However, no disclosure is required for charities that might not have other sources of income. Therefore, if charities income comes from many sources of revenue apart from the principal activity, best practice requires charities to give detail disclosures of every type of income generated as an indication of good governance.

Fund Management

Transparency in disclosures of fund management in the charities annual reports is important because disclosures of information helps the resource provider or public to monitor the management of the fund given to the NPO and the effectiveness of the programs conducted beneficial to society. According to (FATF, 2013) charities can be misuse for the name, status and funding. This can be done by concealing the funds under legitimate purposes and disbursed it to terrorist organizations and activities. Besides, charities might be used to launder money through transmission of funds between multiple locations. Thus, being transparent by disclosing the details of fund distribution, utilization and list of activities in generating the fund are important to build public trust by showing that the particular charities do not involved in money laundering and terrorism financing.

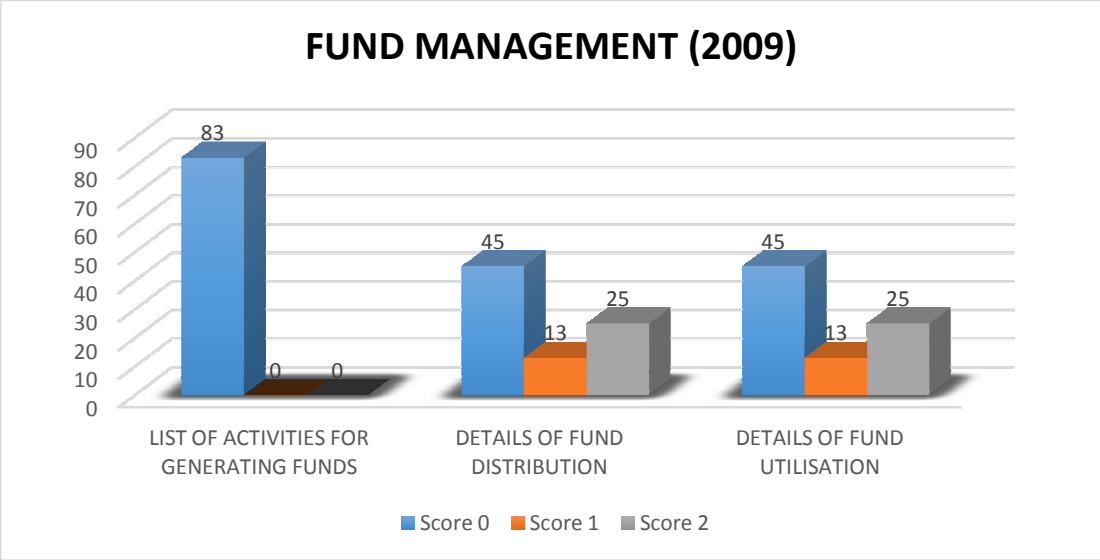

Figure 10: Fund Management Disclosures (2009)

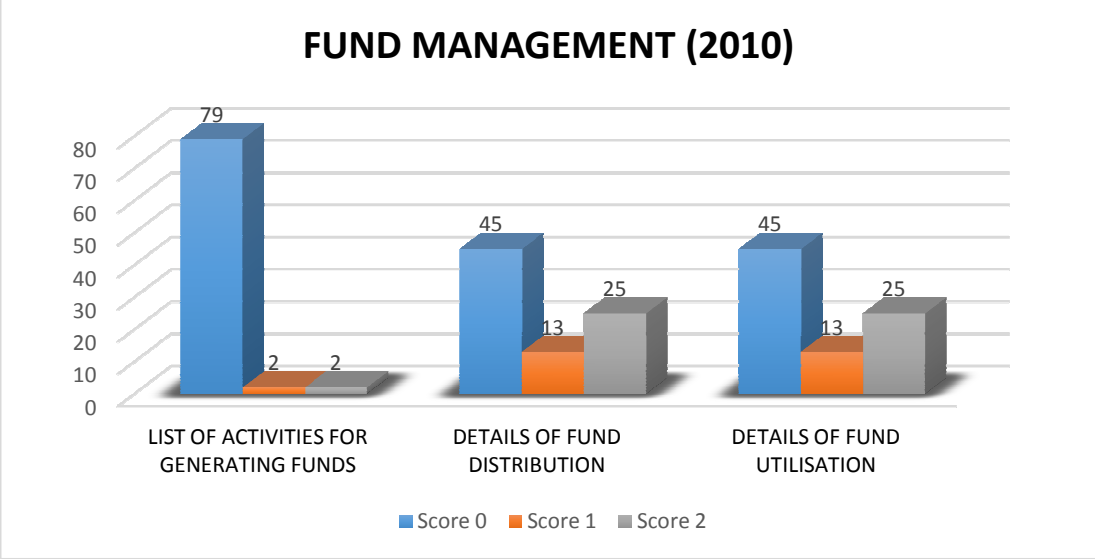

Figure 11: Fund Management Disclosures (2010)

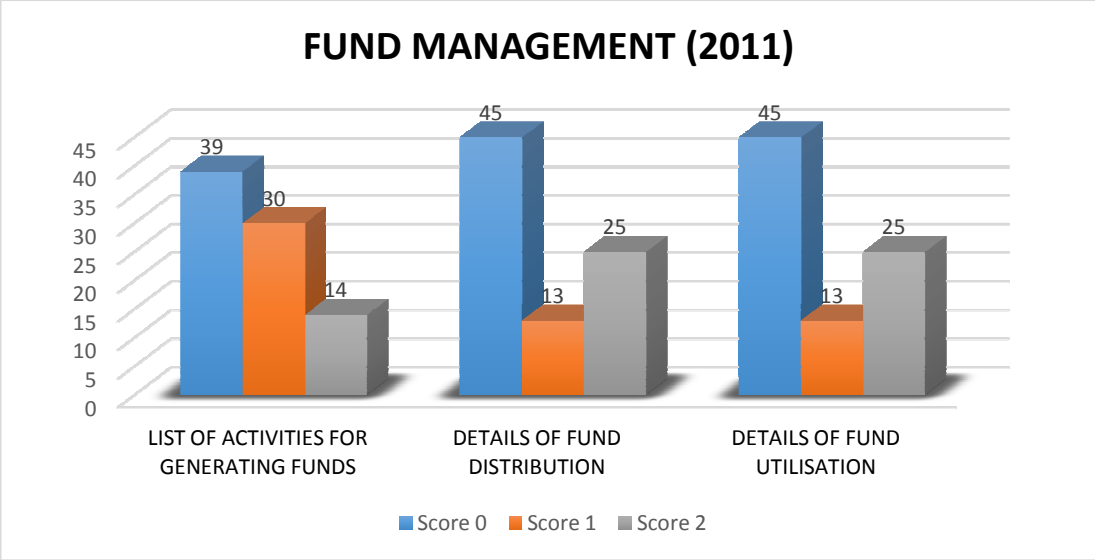

Figure 12: Fund Management Disclosures (2011)

The analysis for year 2009 and 2010 show that, out of 83 charities, none of them disclosed information on the list of activities held to generate charities fund. In 2011, 53% (44) of charities started to disclose activities conducted to generate fund and also explain on how they plan to fund their activities and continue as a going concern in future. However, most of the charities seem to neglect information on the funds distribution and utilizations towards the beneficiaries inside and outside the organizations. From the data analyze, only 46% (38) out of 83 charities give detailed information on how they plan to distribute and utilized their fund throughout the years.

Conclusion

This paper provides a content analysis on the level of information disclose in the annual reports of NPOs in Malaysia, focusing on the information on items related to financial, anti-money laundering and counter terrorism financing. The quality of information disclosed in annual reports could enhance NPOs transparency and accountability towards a more comprehensive reporting. This is indeed an essential part to maintain NPOs credibility in their long run and to create the awareness of the importance of third sector to the community at large. This study found that the level of financial disclosures among NPOs in Malaysia in relation to financial stability can be considered at a moderate level, whereas, disclosure is relatively weak for financial performance and their efficiency. Besides, disclosures of the items related to money laundering and terrorism financing are also weak among the NPOs in terms of disclosing their policies and strategies, sources of revenue and fund management. These indicate several important insights relating to the non-profit sector. First, NPOs in Malaysia are still reluctant to disclose detailed information regarding their activities. This might be due to these information is a voluntary disclosures as stated by the higher authority. Secondly, NPOs in Malaysia have high potential to misuse the information disclosed for money laundering and terrorism financing due to the limited extent of information disclosed in the annual reports. Finally, comprehensive disclosures integrating financial and anti-money laundering can potentially help to improve NPOs' transparency and subsequently their performance for the benefit of the public as a whole.

Taking into accounts the characteristics of NPOs in Malaysia, the development of comprehensive reporting framework is needed to assist and facilitate NPOs in preparing and presenting their annual reports. Reporting guidance or best practices promoted by regulatory authorities are expected to enhance the transparency of annual reports prepared by the NPOs. Therefore, the analysis on the extent of disclosure made by NPOs in Malaysia is essential to support in the development of the comprehensive reporting framework so that it can be used as a guide in developing the appropriate framework and meet the best practice in promoting good governance. However, the results of this study might not be generalized due to limitation of the number of samples selected and it is possible that non-disclosure of some items by some charities are due to no specific framework as guidance in preparing and reporting the annual reports.

Abstract

This study aimed to investigate the relationship between emotional intelligence (EI) and job commitment (JC) of librarians working in public libraries in Malaysia. A total of 180 librarians were selected as the respondents. The instrument used in this study was adapted from Emotional Competency Inventory (ECI) and Job Commitment Questionnaire. All the formulated hypotheses (self-awareness, self-management, social awareness and relationship management) of EI and JC were supported after correlation test and regression analysis were conducted. The findings indicate that a high level of EI can lead to high commitment. Practically, the study implies that an on-going concept of EI and training in the library is needed to produce librarians who are empathetic, willing to accept the opinions of other employees, to provide cooperation and motivate employees. This will indirectly increase commitment and loyalty to serve and work, improving work performance while increasing productivity and job satisfaction in the workplace. Essentially, this study has three main implications: theoretical, methodological and practical that can be used by relevant agencies.

Keywords: Emotional Intelligence, Job Commitment and Malaysian Public Librarian

Introduction

To adapt to various situations and to fulfil one's potential, having the skills and the ability to act is crucial. This assertion is supported by Goleman (1999), who asserts that a person's ability to accept challenges that are inconsistent is closely associated with a person's ability and emotional stability. More importantly, Mayer and Salovey, Bedell, Detweiler, and Mayer (2000) argue the ability to understand and manage oneself and others is known as emotional intelligence (EI). Studies have shown that EI and job satisfaction play an important role in improving the work commitments of individuals and groups

(Mayer& Salovey, 1997; Goleman, 1995; 1999). Hence, it can be argued that EI is a personality trait that should be possessed by every information service provider in order to succeed in his/her career. The ability to understand the level of EI provides librarians with instructions and information in assessing the effectiveness of oneself and is a catalyst in increasing work commitments. There is a possibility that librarians who have high EI may have high work and organizational commitment.

Redmond (2016) asserts that commitment is seen as a necessity in the development of the organization. Awards are given to employees who have high commitment as they usually do everything that is entrusted (David, 2013). In contrast, Kamau (2015) cautions that job satisfaction, job commitment, truancy, lack of concentration and stable-working conditions can affect the quality of work. Disagreeing with Culverson, Bennett, and Durkin (2000) believe that in general, workers are committed to the job and the organization and have no problem to carry out work more than they should. Therefore, every organization as well as public libraries should pay attention to its human resource assets and emphasize commitment to the organization.

In relation to this, the operation of MPLs is generally under the jurisdiction of the state government, however in terms of consultation, policy development, service and supports, the tasks are assigned to the National Library of Malaysia (NLM). As public libraries, their major role is to serve the community in terms of their information needs. In addition, they are also responsible for developing and maintaining the national collections from various resources, providing facilities for their users as well as providing advices concerning library matters. These roles are in line with the national agenda to inspire a culture of knowledge in the development of the country and to foster a reading culture among Malaysians.

It seems that the work at MPLs is complex and there are numerous factors that affect the JC of library employees in providing wide-ranging services to all communities (IFLA/UNESCO, 2001), building a high performance work culture or Key Performance Index (KPI) and Government Transformation Programme (GTP), (Jabatan Perdana Menteri, 2010 and Najib, 2010) and dealing with a more demanding clientele (Jomo & Wee, 2004), along with multi-tasking.Awareness of the importance of planning, allocation and use of resources are factors that influence employee commitment in public organizations and can determine the ability of the organization (Mondy & Noe,2005; Culverson, 2002).

Given the importance of EI and its role in behavior and practice, the need for more research can be felt to confirm or refute previous findings. Hence, this study has been conducted with the aim of investigating the relationship between the dimensions of EI and JC of librarians in MPLs. Identifying a relationship between EI and JC can assist early employees programs from the beginning of the hiring process in order to invest resources on recruitment, selection, and training for librarians who will exhibit a long-term commitment to their job.

Literature Review

Emotional Intelligence

According to Goleman (1998), EI is the ability of individuals to identify and manage their own emotions and motivate themselves and identify the emotions of others and establish friendly relations with them. Noriah (2005) stipulates that intelligence is one set of emotional competencies or skill-based emotions that allow someone to manage life better. This intelligence involves the ability to (i) explore one's own emotions to understand and assess the situation itself, (ii) use emotional tendency, that is to guide or facilitate the achievement of an objective, (iii) recognize others' feelings, needs, wants, problems or annoyance, (iv) recognize the importance of religion as a pioneer life, and (vi) use life experience (oneself or a client's) as a guide in solving problems. In the context of this study, EI is measured by four domains of EI (self-awareness, self management, social awareness and relationship management).

An organization may experience non-productive periods because its employees lack EI skills and a positive attitude. Therefore, each individual in the workplace should be given exposure and skills on how

to build and improve his/her EI. Individuals who are emotionally intelligent and have a positive attitude appear fit and motivated and are able to control themselves and the situation. High personal and work productivity and integrity help to build a winning organization.

Job Commitment

Overview of Job Commitment

Commitment is a word often emphasized in order to produce excellent workers. To nurture commitment, employees should learn the correct and appropriate coping strategies in planning an action plan to deliver the given task. Commitment is defined as a strong the relationship between workers and the organization (Colarelli & Bishop, 1990). Commitment viewed from various perspectives refers to a variety of criteria, circumstances and the employee behaviour (Hernon, 2009). Typically, there are symbioses with the requirements of the organization. Employee commitment is to establish links between both. Organizations need ability, efficiency, diligence and loyalty of its members while for the workers, the need to meet their needs, at least the basic requirements, before they can show commitment (Oludeyi, O. S., 2015).

Organizations usually highly appreciate the commitment of its employees as employees that have a strong commitment tend to be associated with increased productivity, job satisfaction, less absenteeism rates, and stable work atmosphere (Rakowska, A., Juana-Espinosa, S.de and Valdés-Conca, J., 2016). In fact, it is easier for organizations to achieve additional contributions such as innovation and creativity when the workers are committed, which, in turn, will contribute to higher ability of the organization (Jafferian ,. S. L. (2016). Therefore, commitment to the organization should be taken into account as soon as possible, as each organization should give attention to its human resource assets.

Employee commitment to the task can be accomplished if they comply with the discipline and the work ethics and have a positive attitude and judgment in carrying out the task entrusted. The value of this positive attitude can be measured when a person feels good and happy to start the day with work. A work environment that is supported by this kind of attitude and excitement can create a positive practice that transforms work as a form of worship, induces high commitment among employees; motivates ready cooperation between employers and employees (Mondy & Noe, 2005).

When an employee joins an organization, it is assumed that the individual has agreed to contribute his/her efforts achieve the goals of the organization. Therefore, the individual must give full commitment to the organization as organizational productivity can be increased through his assuming responsibility. Commitment can be defined as a psychological bond between the employee and the organization and a person's desire to remain with the organization (Simosi, Xenikou, 2010). Yahya, Johari, Adnan, Jesus, and David (2008) refer to the interpretation by Sinani, S. (2016) as commitment to strong individual wishes to remain a member of an organization despite opportunities to change jobs. Therefore, there are two aspects that can be interpreted as commitment to organization: aspects of loyalty and engagement aspects (Cohen & Higgins, 2007). Aspects of loyalty are affection and a sense of pride in the organization and wanting to remain a part of the organization while aspects of participation are sought without pressing the interest of the organization (Yavuz, 2010).

Determinants of Job Commitment

According to Meyer and Allen (1997), JC is closely related to emotions, ideas, philosophy and values held or internalized by the individual while performing his/her duties. Porter also defines JC and Smith (1976, p. 89) cited in Mishra, and Shyam (2005) as:

- a strong belief in and acceptance of the individual‟s goals and values;
- a willingness to exert considerable even if everyone on behalf of the organization;

- a strong desire to maintain membership in the organization.

Alnıaçıka Alnıaçıka, Akçinb and Erat (2012) argue that career motivation theory examined the effects of individual, situational and extra-work variables on JC. These three types of determinants are defined as follow (London, M., & Noe, R. A. (1997):

1) Individual variables are defined as needs, interests, and personality variables potentially relevant to one's career;
2) Situational variables are work environment factors that can influence career motivation, such as "staffing policies and procedures, leadership style, job design, group cohesiveness, career development programs, and the compensation system" (p. 621);
3) Extra work variables are mostly related to the demands of work and family.

There are multiple determinants that influence JC including organizational culture (Sinani, 2016) competence and motivation (Fabiene, E. E. and Kachchhap, S. L., 2016), gender (Razzaq, M. A. and Ullah, N., 2014), education and organizational culture and loyalty (Oludeyi, O. S., 2015), absenteeism (Brunetto et al., 2012), and environmental settings (Ingersoll et al., 2002).

Workers in the civil service specifically in public libraries contribute to achieving the effectiveness of the delivery system of the country. This group is responsible for ensuring that programs, services, activities and agenda of the library can be realized. In this exercise, employees of the public library have a dual role, not only as an organization but also act as the aspirations of the government in developing the country (Garmer, 2014). Therefore, this sector is not only part of the foundation of national development but also a driving force in achieving the government's vision and mission. A study on employee commitment to the organization is not new. Studies by Varona (1996), Barrows and Wesson (2001) and Culverson (2002) associate employees with various levels of commitment factor. In fact, studies by Razali (1993; 1996) and Jaye (1999) specifically examine the lack of commitment in the public sector in Malaysia.

However, there are issues with the quality of work within a library compared to other sectors that offer better rewards (Razali 1993). The scenario of workers moving to a better organization is not something new. The remuneration, benefits and privileges offered in the private sector are more favorable than the offer of the public sector is a common fact. Thus, the effort to retain employees as valuable assets is constantly evolving over time and is extremely important for the organization, particularly the public library. Therefore, factors affecting employee commitment to the organization should be studied and made known. High intent to leave was found to be influenced by friends, but also feelings of job stress and "being burnt out" (Ryan, Ghazali & Mohsin, 2011). Studies on the JC determinants showed multiple findings as indicated in Table 1.

Job Commitment among Librarians

In the context of librarianship, studies examining JC include Burd (2003); Luzius and Ard (2006); Bromann (2004); Burnam and Green (1991); Popoola and Oyewumi, O.O. (2006) and Millard (2003). Gboyega and Popoola (2010) have shown that work commitments are influenced by demographic factors. Furthermore, there are studies like Millard (2003) which revealed that the commitment of librarians at the center of English Canada is more important than other factors (organizational commitment, personal factors, or economic factors) to their retention in the librarian profession. In line with Millard, the findings of Burd (2003) also revealed how librarians will not leave their posts (committed) and are satisfied in the library due to factors such as organizations that support participatory management, open communication, opportunities for achievement, and relationships built on honesty and trust.

These findings are supported by Millard (2003) who argued that the key to the library and to continue to serve in their profession is a career commitment. For Hoggan (2003), he is compelled to solve problems such as bureaucracy; budgetary issues, poor supervision and leadership, faculty status and burnout as these factors hinder eternal loyalty of librarians to serve in libraries. In contrast, the study by McCormick and Tiffin (1994) which shows that employees like their values realized in the workplace and having a positive attitude is a factor to commit to the library. Additionally, Martins (1991) found economic factors, salary, status, promotion, and lack of social security also affected the career commitment, work motivation and effectiveness of a librarian. Factors such as working conditions, rewards, job security, and opportunities for promotion, social status, salary, social services, powers, and responsibilities are part of a librarian's professional commitments (Kaya, 1995). Oberg (1995) concludes that the status of librarians should be defined, the campaign must rely on objective criteria, and the development of technology can be used to inject new ideas. Motivation factor can also be considered as a factor influencing the level of self-efficacy and career commitment (Popoola, Tella & Ayeni, 2007).

Emotional Intelligence and Job Commitment

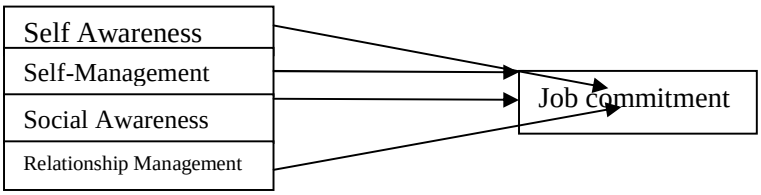
Past analyses have tried to find if there is a relationship between the EI of a public employee and their job commitment, with diverse results. Without doubt EI has been found to be one of the contributing factors to job commitment. Nonetheless these studies involved professionals other than librarians as exhibited in Table 2. In the context of librarians, the influence of EI on JC is yet to be studied. Contemplating that the landscape is as such for librarians, the researchers argued that EI may also be persuasive in predicting the JC of librarians.

Table 2: Studies Linking EI and Job Commitment

Author	Subject Study	Findings
Brunetto et al. (2012)	Policemen	The survey, involving 193 police officers in Australia found that there is a positive relationship between job satisfaction and wellness, employee involvement and commitment to the organization
Jin Kyoung Ma (2016)	Clinical nurses	There were significant correlation between emotional intelligence and organizational commitment of coaching types excluding the commanding type.
University of Haifa. (2016)	Public services	EI positively influences the motivation of public service workers, which in turn increases the level of their affective commitment

Chehrazi, S & Shakib, M. (2014)	Employees of united bus company	Using structural equation modeling, the study has confirmed that emotional intelligence influenced on organizational citizenship behavior and commitment.
Veisi and Alizadeh (2012)	Oil Products	A positive relationship was gained between self-control, unanimity, social skills with emotional and professional commitment.
Jafferian ,. S. L. (2016)	Substance Abuse Treatment Centers	Results showed that participants who rated their supervisor high on emotional intelligence were less likely to report an intention to leave than were participants who rated their supervisor low on emotional intelligence.

Given the range of empirical evidence on the relationship between EI and JC, this study examines the relationship between EI and JC by changing the setting to the library service using a different approach. Therefore, the following hypotheses were developed:



H1 - Self Awareness of EI is significantly related to JC
H2 - Self-management of EI is significantly related to JC
H3 - Social Awareness of EI is significantly related to JC
H4 - Relationship management of EI is significantly related to JC

Methodology

This study adopted a survey research design using questionnaires. According to Salovey et al. (2000), research on emotional intelligence is a study to enhance abilities, self-assessment and efficiency; therefore this type of research is more appropriate. The focus of the study is librarians in Malaysia serving in the public libraries including the National Library. A total of 180 respondents were involved, covering a wide range of grades, experiences and states (in Malaysia). Stratified sampling method was used given the large population. In this study, the researchers used a questionnaire for collecting data regarding emotional intelligence, and employee commitment.

The questionnaire used in this study contains five sections:

Part A: The questionnaire measures emotional intelligence via Emotional Competence Inventory (ECI) built by Boyatzis, Goleman, and HayMcBer (1999). [Self-Awareness, Self-Management, Social Awareness and Relationship Management]. Part B: The questionnaire measures modified work commitments (Mowday, Steers, & Porter, 1979) and Section C is on the profile of respondents. The ECI test tool has a high reliability of .93 Cronbach alpha values. For each dimension, the reliability is .88 for the dimension of self-awareness, .85 for self-management, social awareness and .86 to .91 for relationship management. The test tool also has the commitment to work reliability of 0.78.

Two types of statistics were used in data analysis, descriptive and inferential statistics. Descriptive statistics of the data were analyzed using frequency distribution, percentage, mean and other calculations, which can reflect the distribution of the data more clearly. Inferential statistics were used to test hypotheses formed in study, which is to see the relationship between the variables. Level of 0.05 ($p < 0.05$) was defined in this study as a significant level to accept or reject a hypothesis. In this study the researchers formed four hypotheses to be tested.

Findings

The Relationship between EI and Job Commitment

Numerous past studies have investigated the relationship between EI and organizational commitment but limited studies have been done in the context of job commitment. Hence this study further identifies the relationship between EI and job commitment. As shown in Table 3, the correlation analysis between the abovementioned variables against the JC variable produced a moderate correlation. However these correlations between variables exist and are still significant at the 0.001 level.

The correlation *r* between the four dimensions of EI and Job Commitment (JC) of occupational performance is illustrated in Table 3. The purpose of the study is to examine whether Emotional Intelligence (EI) is significantly related to the JC of Malaysian public librarians by focusing on four major aspects of EI, that are self-awareness, self-management, social awareness and relationship management. Noticeably, all dimensions show a moderate relationship and correlation or above 0.5 (Cohen, 1988). The strongest relationship is between self-management and JC, which stood at 0.578***r*-value. The relationship between self-awareness and JC and between social awareness and JC, recorded a confident Pearson *r-value* of 0.576**. The lowest *r*-value is the relationship between relationship management and JC, which scored a Pearson *r-value* of 0.568**. To test the hypotheses H1, H2, H3 and H4 in this study, regression analysis is conducted as discussed in subsections 4.1.1 to 4.1.4. The results of the analysis, which are shown in Table 4 below, suggest that all the four formulated hypotheses are supported, justified by the *p* values, which are less than 0.05.

Table 3: Results of the Reliability and Correlation Analysis

		Correlations				
Variables	**Cronbach Alpha**	**SAW**	**SMA**	**SOW**	**RMG**	**JCT**
Self_Awareness (SAW)	0.856	1	0.690**	0.585**	0.563**	0.576**

Sig.	0.000	0.000	0.000	0.000

The Relationship between Self-Awareness and Job Commitment

To determine the relationship between self-awareness and JC, the study hypothesizes *H1: Self-awareness is significantly related to job commitment.* Table 4 depicts that the *r* value is 0.232 which can be interpreted as positive with a very low correlation between the variables of self-awareness of EI and JC. Bivariate linear regression analysis found that self -awareness is significantly related JC (R square = .017, F = 23.49, p = .00). In other words, the higher the librarian's self-awareness components, the better JC would be. The research findings express that there is a relation between self-awareness and employees, self-awareness in a way that these dimensions of EI also have a positive effect on JC. H2 therefore is supported. However, only two percent of variance in the dependent variable was explained by self-awareness, suggesting that the predictive relationship between the two is weak. This result provides some evidences in explaining the relationship between public librarians' EI specifically self-awareness and JC which is parallel with other studies. (eg. Ragins, Cotton & Miller,2000; Erez & Judge,2003; Pawar,2009). Without doubt this finding is similar to the study conducted by Mousavi, et al. (2012) and Maheswari and Krishnan (2012) who found the relationship between the related dimension of self-awareness and JC.

The Relationship between Self-Management and Job Commitment

In determining the relationship between self-management and job commitment, it is postulated that *H2: Self-management is significantly related to job commitment.* The Bivariate regression analysis which is shown in Table 4 indicates that self-management is significantly related to JC (R square = .024, F = 56.64, p = .00. Hence, H2 is also supported, thus confirming the previous findings of Davis et al. (2000); Hoekman, McCormick, & Barnett (2005); Stroud (2009), Fatima, Imran and Zahir (2010) and Duccan (2011) and revealed a positive relationship between the variables within self-management such as emotional self-control, transparency, adaptability, achievement orientation and optimism with JC.

The Relationship between Social Awareness and Job Commitment

The study also posits that social awareness of EI is significantly related to JC. Thus it is hypothesized that*H3: Social awareness is significantly related to job commitment.* Based on the result of the correlation analysis as presented in Table 3 and regression analysis in Table 4, the hypothesis H3 is evidently supported. Social awareness is also measured as a positive significant predictor of JC as 39.3% of the variation in it can be explained by $F = 32.53$, p =.00 social awareness alone. H3 therefore is supported despite the predictive indicator between the two is just moderate but positive. In sum, aforementioned outcomes provide supporting evidence for accepting H3 hence further strengthening the findings of Pool (2000); Brown, George-Current and Smith (2003); Lytle and Timmerman (2006) that exposed social awareness competency of empathy, organizational awareness and service orientation have a positive and significant relationship with JC.

The Relationship between Relationship Management and Job Commitment

Relationship management inculcates a set of competencies, which include essential social skills, analysing and influencing others and inducing desirable responses in others. Effective relationship management helps in developing others, which is a hallmark of management and leads to JC within the organization (Reed, 2005). This aspect is also addressed in this study, which posits that *H4: Relationship management is significantly related to job commitment.*

In determining the relationship between relationship management and JC, the correlation analysis (Table 3) and regression analysis (Table 4) unveiled that Pearson's $r = 0.568^{**}$, while $R^2 = 0.49$, with F = 56.443 and p = 0.000. These figures denote a significant relationship between management and JC. Thus, H4 is also supported. Upon further inspection of the relationship between these variables, it is apparently moderate. This result is similar to past studies (eg. Rashear et al. (2006), Raabe and Beehr (2003); Bass (2002); Hysong et al. (2008); Posthuma (2011); Cohen (2007); Fosmire (2008); Grassian and Kaploowitz

(2005) and Hernon (2007) that determined the various dimensions of relationship management (such as transformational leadership, influence, developing others, change catalyst, conflict management, teamwork and collaboration and communication) are related to JC. Similarly, the current study found this factor to be linked to JC.

Discussions and Conclusion

The results show a correlation between EI and JC. This indicates a significant relationship between EI and the level of JC of public librarians in Malaysia. However, the value of this correlation is moderate, indicating EI is one of the main factors working at the level of commitment of librarians. These findings do support Adeyemo (2007), Humphreys, Brunsen and Davis (2005), Nikolaou and Tsaousis (2002), Singh (2004) and Sinha and Jain (2004). According to them, an organization that practices the competencies of EI such as self-awareness, self -management, social awareness and relationship management and concern for humanity (humanistic), enables its employees to continue to remain resilient in the organization. With this, each employee will provide maximum cooperation and voluntary participation, thus contributing to JC.

They will be more committed when they realize the strengths in themselves can overcome their weaknesses. Appropriate training can make them more committed to provide the needed services. Awareness of self-improvement makes them highly committed to thinking about the willingness of the management. This is supported by Goleman (1998) who explains that the awareness of self as a component of EI is central to the work commitments of the organization. Employees who are aware of their purpose will have a clear understanding and are committed in relation to their suitability to organizational goals.

On the other hand, librarians who consider themselves not as part of the members of the library services or self-management will show a low level of commitment. In other words, self-management of EI is linked to JC. New staff in the library usually knows little about the role of such organizations and have problems in adapting to others. They also lack integrity, have less initiative and are pessimistic in the workplace. New library staff usually has less understanding and fewer clear pictures of the tasks given to them. According to Warshaw (1979) in Othman Mohd. Yunus (1986), individuals that do not know how to adapt in an organization and do not know what benefits to be gained by them, give less attention to their responsibilities or lack commitment to the organization. Hence, the relationship between self-management and JC is validated and parallel to studies done by Fatima, Imran and Zahir (2010), Davis et al. (2000), Duccan (2011), Stroud (2009) and Hoekman, McCormick and Barnett (2005).

A positive work culture within the library will be able to attract librarians to be committed, loyal and feel proud of their work, and can ultimately result in doing the best. In this way, it can help improve knowledge, skills and boost confidence so that librarians become more valuable to the library and the profession and eventually can enhance a sense of pride in the services.

Given the tendency of service workers to be committed to helping others, it is not surprising that JC has significant relationships with EI. Normative JC focuses on the individuals' obligation to their occupation. The findings of the present study conclude that good communication with others; great teamwork and collaboration, using emotions in solving problems, and expressing emotions adaptively have significant correlation to JC. Using emotions in creating good relationships with others has the strongest significant correlation suggesting librarians who are able to use this skill are also likely to have a stronger commitment to their occupation based on obligation and networking. A possible explanation for this may be the strong sense of purpose that many service workers have when choosing to work in the profession.

The findings show that social awareness and relationship management fit the concept and theoretical issues raised by Goleman (1995), which involves social competence. The social competent is to identify themselves, organize themselves emotionally, motivate themselves, recognize emotions of others and develop social relationships. All these attributes, if owned by librarians will help prevent them to stop

working in their current careers. In relation to this Goleman (1998) agreed that the emotional competencies are two times more important than cognitive ability in determining employee excellence. Therefore, in the case of public librarians, EI can predict success in any place, including in the workplace. Social awareness and relationship management of EI can help individuals to work in teams and work more effectively and be committed to each other.

Abstract

Within the supply chain, the customer does not simply buy parts or services from suppliers, but also buys supplier capabilities, which results in quality products and services. Having a tool that handles the Inspection as well as the Nonconformance, Complaint, Corrective Action and Concession processes is key to successfully track the supplier performance. Taking as a case study a Supplier Quality Management (SQM) currently in operation in an Original Equipment Manufacturer (OEM) for automotive industry, this paper presents a platform to support a Supplier Quality Management System (SQMS), that fits the technical specification ISO/TS 16949 requirements. This prototype is composed by a web platform and a mobile App, having flexibility and mobility as key main characteristics.

Keywords: Supplier Quality, Total Quality Management, ISO/TS 16949.

Introduction

The automotive production of modern days, had come a long way since it was first developed and the quality became more important in this industry, with the start of the mass production era. The use of relevant tools according the organization's needs, became strategic and essential for the industry in the competitive environment of todays. Using the proper tools and optimizing processes, industries can improve their performance and thereby increase customer satisfaction and enhance supply chain. The entire automotive industry pursues the adoption of standards, specifications, procedures and other practices in order to improve the final quality of its products. However, they still have difficulties in finding the right tools to their production environment and often these processes are carried out with less appropriate tools to ensure the good practices required.

An organization spends substantial time and money, purchasing raw materials and managing suppliers. Therefore, supplier quality, meaning quality parts, on time delivery, on right quantity, can substantially affect the overall quality and cost of a product. We believe that quality management procedures and tools are instruments that help to increase and improve the efficiency throughout the complete supplier chain.

A company cannot produce a quality product if the components of which it is made are faulty. One of the keys to obtain high quality products is to work with the suppliers to achieve the same quality level has attained within the organization and this is why supplier quality management is mandatory in the complete chain of automotive industry, and it is one of the requirements of the technical specification ISO/TS 16949 (ISO, 2013). To apply this method successfully, the proper tools play a decisive role. This paper presents a prototype for a supplier quality management system of model defined in (Sousa, Cunha, Morais, & Gomes, 2015), which was based case study of a Portuguese company in the auto industry that supplies parts to the major automobile manufacturers. The prototype follows the ISTO/TS 16949 standard, implementing the functioning of their processes.

With this prototype, we expect to improve the evaluation and selection of the supplier network and increase the efficiency of approval process of new suppliers. Handling the inspections and non-

conformance will help the tracking and management of raw material quality, ensuring that all the non-conformance will be addressed and that appropriate actions will be requested.

The remainder of this paper is structured as follows: section 2 (background) discusses the Total Quality Management (TQM) and ISO/TS 16949. Then we present the modulation of SQMS platform and chosen architecture. Sections 4 and 5 present the web application and mobile application developed. Finally, we provide some discussion and future work.

Background

The quality term exists since always and is a subjective concept that is related to the perception of each individual and related to several factors such as culture, needs and expectations. In the past the quality of a product only meant to comply with the customer's requirements. Since industrial revolution, the quality has developed until the present day mainly through four eras (Dahlgaard, Kristensen, & Kanji, 2002): age of inspection, focused on the product; age of statistical quality control, focused on the process; age of quality assurance, focused on the system; and age of Total Quality Management, focused on the business (Bovas Abraham, 1998):

- age of inspection: by monitoring the parts, only focused in the separation of "Good" and "Bad" parts;
- age of statistical quality control: applied statistical techniques for process control in order to identify and minimize or remove special causes of variation that could affect the product. Emerged the management style where the defect causes are identified and actions in them are taken.
- quality assurance era: the cost of rework and consumer displeasure are considered. A preventive management started with positive implications in terms of quality and consequently resulting in the reduction of waste.
- age of TQM: it is a natural evolution of the previous three stages, integrating them, being however wider as it applies to quality in all areas of a business, including sales, finance, purchasing, among others and not only the productive ones.

Total Quality Management definition

The term TQM stated to be used in the mid of 80s and became recognized part of the quality related language in the late the same decade (Martínez-Lorente, Dewhurst, & Dale, 1998). TQM is a process that was applied successfully in industries in the US in the 1980s. By using the process, large companies, such as Texas Instruments, Xerox, IBM and Motorola, were able to improve their business positions by overcoming threats from global competition and other changes in the business environment (Lozier & Teeter, 1996). The TQM is a comprehensive and structured approach to organizational management focusing on the maintenance and continuous improvement of products, people, services and processes with the goal to meet or exceed customer expectations (Flynn, Schroeder, & Sakakibara, 1994; Goetsch & Davis, 1997; Shiba, Walden, & Graham, 1993).

TQM is a philosophy with customer focus and results orientation with the involvement of all. It is a systematic approach to quality management across the business, which is based on the use of tools and techniques of continuous improvement in all organizational processes. It is in this environment that global automotive industry fits, which requires a high level of product quality, productivity and competitiveness, having as engine the continuous improvement (Asif, Awan, Khan, & Ahmad, 2013; Lanza, 1997; Li, Markowski, Xu, & Markowski, 2008)..

To achieve these goals, the vehicle manufacturers insist that their suppliers need to be certified to the quality management standard known as ISO/TS 16949 (Sroufea & Curkovicb, 2007). This standard was

developed by the industry, the IATF (International Automotive Task Force), to stimulate the improvement of the supply chain (Radley M. Smith, Roderick A. Munro, 2004). The purpose of ISO/TS 16949 is the development of a quality management system that generate continuous improvement through avoidance of defects, reduction of deviation and waste minimization, on the entire supply chain of the automotive industry (Foster Jr., 2008; Hoyle, 2005). By applying this quality system standard, automotive manufacturers could offer superior products and good services to customers. It is in this context that supplier quality management has become mandatory, in an industry that needs to ensure same quality level in all steps of complete supply chain.

SQMS Model and Architecture

In (Sousa et al., 2015), were presented and described the procedures that are part of the SQM currently in operation in an OEM for automotive industry in the north of Portugal and the way they are implemented.

In this section it will be presented the proposed model and architecture that will support this model.

Modulation of SQMS

The Fig 1, shows the class diagram in Unified Modelling Language to describe the classes and their relationships. This diagram was the start point to define the prototype class structure.

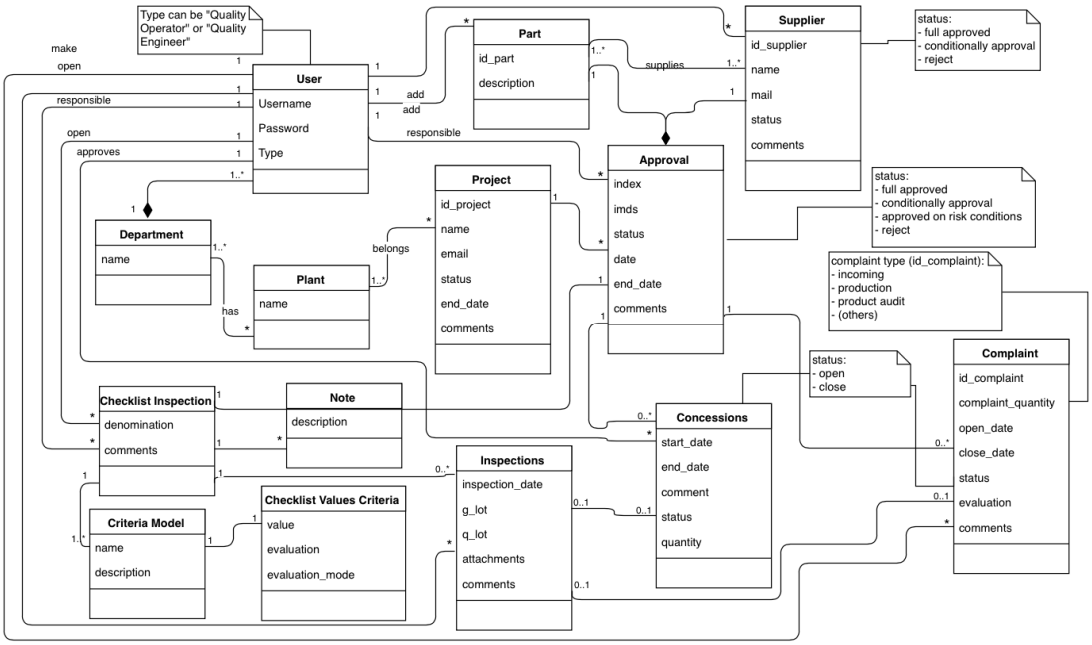

Fig 1: Class Diagram of the SQMS Prototype

The Fig 2, shows the relational model diagram of the database of the SQMS prototype. The database is composed by 28 tables to hold all the system data. Following, it will be described some of the most relevant information of the main tables of the database. The table Approval hold all the parts approvals identified univocally by the part id, supplier id and index. All the parts need to be approved to be part of the system. The table HistoricalApproval records all changes that happen in the status during the part approval process, and who made these changes. The table ProjectPlan indicates which are the projects

that belong to each plant of the company. A project may be associated with more than one plant. The table InspectionChecklist saves the inspection checklists of the parts, each part has only one inspection checklist. The table CriteriaModel relates the checklist criteria with the inspection checklist and the table ChecklistValuesCriteria contains the collected values during an inspection. The table Inspection relates the inspection made with the parts, one part can be inspected several times. The Complaints table records all claims made during an inspection or approval. An inspection or approval may raise to several complaints.

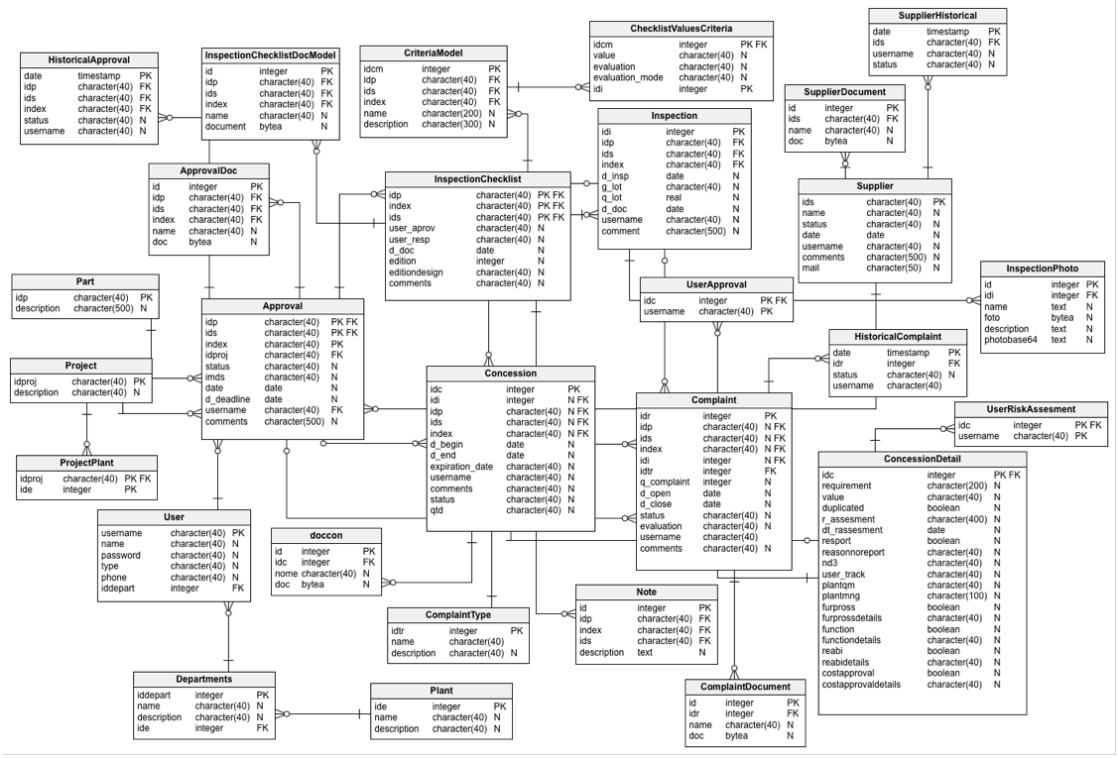

Fig 2: Database Entity Relationship Model Diagram.

Architecture of SQMS

To implement the model defined in (Sousa et al., 2015), we implemented a platform set by two parts (Fig 3): a web platform and a mobile app. This architecture is supported mainly by a Tomcat Application Server, a PostgresSQL database to storage the data and the already existing Directory Server to authenticate the users. The SQMS was built using the Google Web Toolkit (Google, 2014), Android SDK, and Java language.

To provide the mobility required to do some tasks out of the office area, we also implemented a mobile app to run on a tablet. This app will be used by the quality operators to consult inspection checklists and launch inspections data directly on the system. It also allows to add photos, video or audio to the inspection guides to generate the claims reports to the supplier.

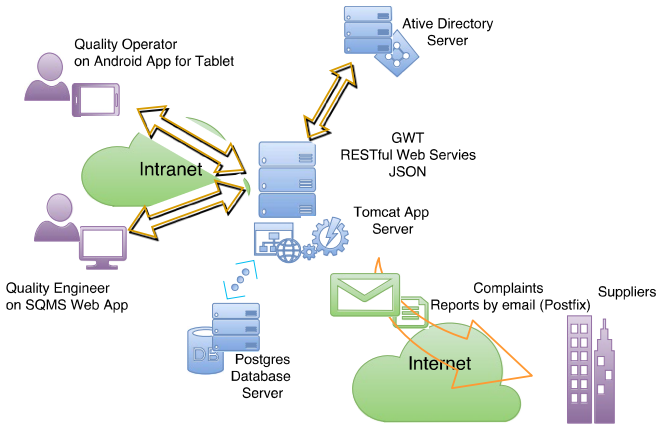

Fig 3: High Level Architecture to support the SQMS model.

Web Application

One of the SQMS prototype parts developed was a Web platform. The choice to implement a web based architecture brings several advantages already described in (Sousa et al., 2015). In order to help the system to be more usable to all users it also supports internationalization to adapt to the different languages because the organization has plants in different countries. The SQMS prototype it is in advanced stage, and this section will present some of the most important options of it.

The Fig 4, shows the main window after the user has logged in. The left side of page has a vertical menu with the main options divided in three main sections:

- Searches: which allows the user to quickly search by parts approval, inspections, claims, concessions, parts, and projects. This feature was requested by the quality team to easily find some of the items by the part id.
- Data Management which is divided in the fowling options: Approvals, Inspections, Complaints, Concessions, Suppliers, Parts and Projects. All these options allow the data management of each of them.
- Administration which offers the fowling options: Users, Logs, Plants, Departments and Complaints Type, related with the platform administration.

On the right side of the main page lies the desktop area based on Tab Layout Panel that will be opened by the selected option. When the employee logs on the application, will see a panel that can not be closed, with all the alerts about pending claims, expired concessions or open approvals. If the user finds that the procedure concerning to one of these alerts can be updated, he has the chance to do it directly in this panel. Such as in the case: if the 8D format report is received from the supplier, and it was approved by the quality engineers, the user can update immediately the claim to the closed state.

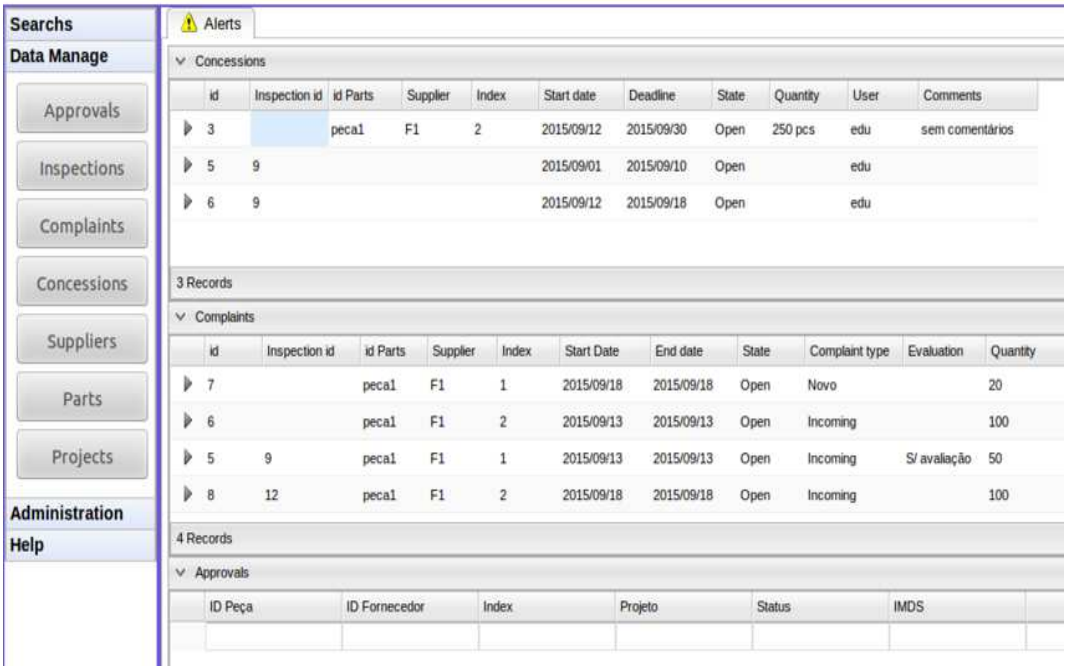

Fig 4: SQMS Alert panel.

The Fig 5 show the concession panel where is possible to view or edit all the concession, or to add a new concession. A new concession is created in case of deviations from product or process characteristics and is always limited in quantity or time that parts in that status can be used. For each concession an action plan is needed to detect and eliminate the root cause of deviation, so new several documents can be uploaded related to that concession.

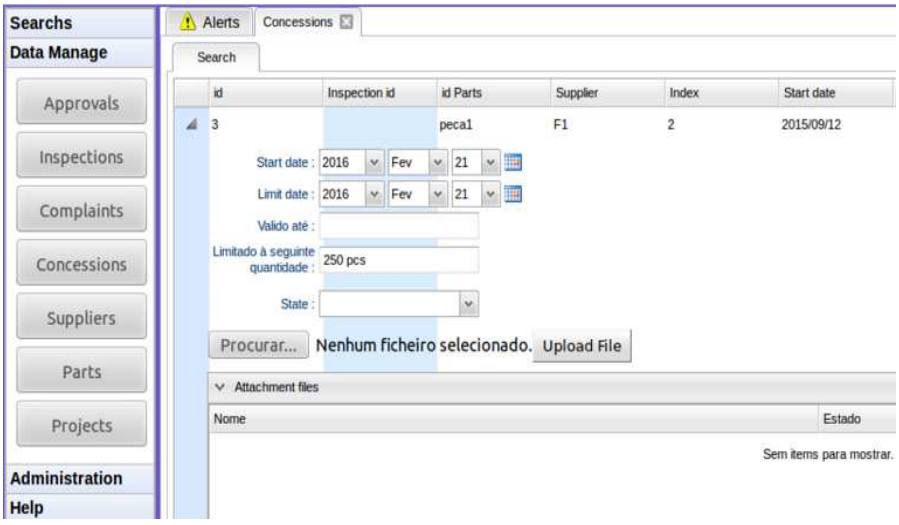

Fig 5: SQMS Concessions panel.

The Fig 6, shows Inspection Panel where is possible to view all, edit or add a new inspection. This feature is also provided by SQMS mobile App, that allows to make inspections in the production line or incoming warehouse. The inspections are done with the support of checklist form that contains the items to evaluate and its inspection criteria and record through the SQMS mobile App form. Usually photos are attached and notes are taken to better describe the non-conform part, if found. If a new checklist model is needed to make new inspection part, its possible to make a new checklist model that will be available to the quality operators after the approve of the quality manager.

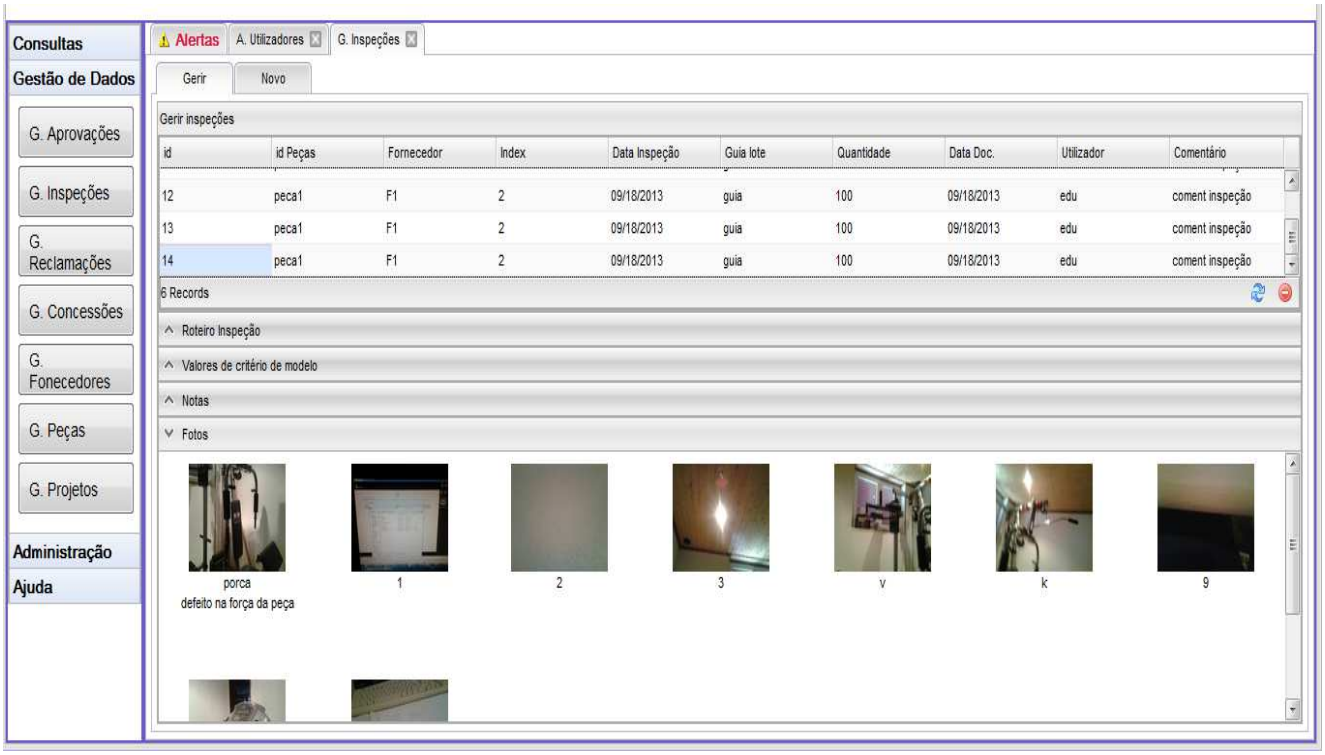

Fig 6: SQMS Inspections panel.

The Fig 7, illustrate the panel view, edit, delete or add a new supplier to the system. Because the approval of a new supplier has done by a defined procedure and an established checklist to evaluate the general capabilities of supplier, this new supplier options allows to attach some documents like contracts, NDA (Non-Disclosure Agreements), audit results, among others.

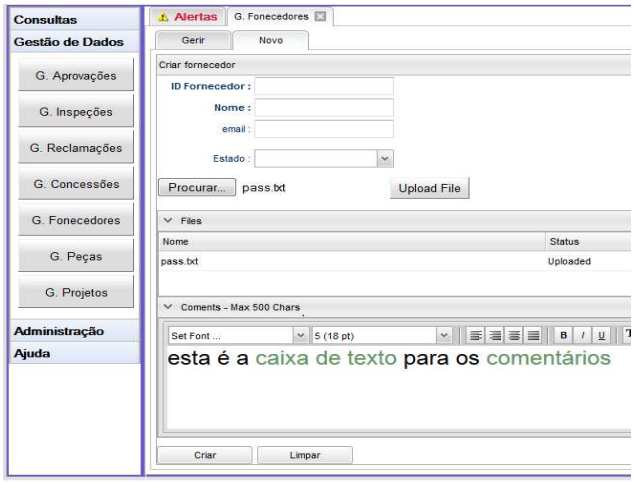

Fig 7: SQMS Supplier panel.

The Fig 8, shows the complaint panel that display all the open complaints, allowing to create, edit or delete a complaint. Several reports describing the failure can be attached and a report is created to the supplier. When an answer from the supplier is received its analyzed by the quality engineer. If accepted, then the first parts received after actions implemented need to be inspected and positive evaluated that complaint can be closed. The closed complaints do not appear in the panel and only be accessible in the historical panel.

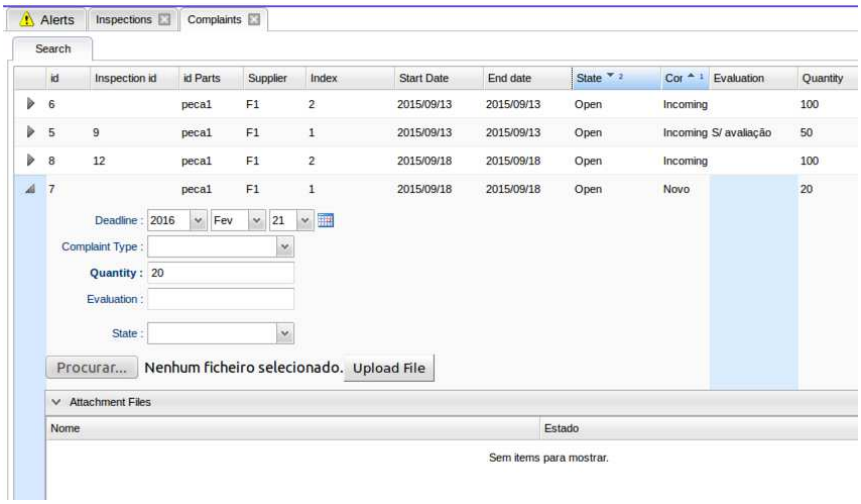

Fig 8: SQMS Complaints panel.

The Fig 9, shows the historic of all operations done in the system. Each record shows the id operation, date and the user which made the operation.

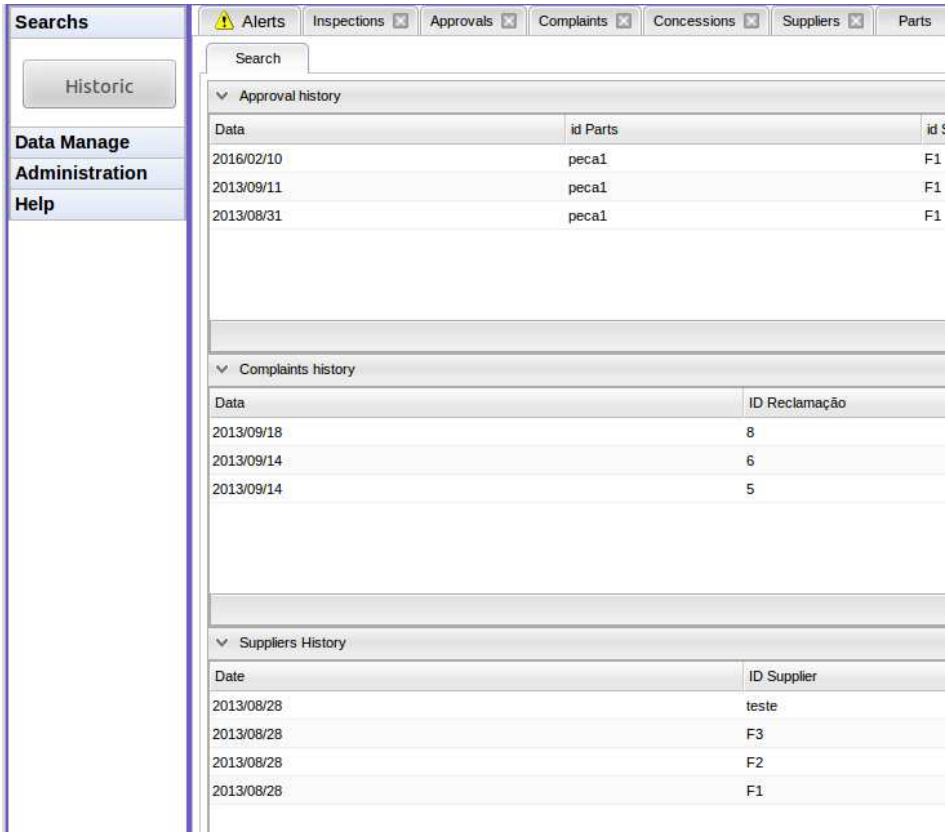

Fig 9: SQMS Historic panel.

Mobile App

A mobile App to be used on a tablet was developed to allow the quality operator access and manage data of the SQMS platform. Some of the most import features are to consult the checklist that contains the items to evaluate and its inspection criteria. The quality operators can also use this app when they are in the production line or incoming warehouse making inspections and record these inspection data using a form and save then into the system database (Fig 10 – left screen). If a non-conform part is found the deviation need to be analyzed and according severity of the defect the parts will be blocked and claimed to the supplier or a concession will be issued. During the inspection process, old inspections or open complaint related to that part can be checked to assist the quality operator (Fig 10 – right screen). This feature solves a common problem that have been reported, that in different plants of the same group, were found defects in common parts and this was handled independently, consuming time and resources.

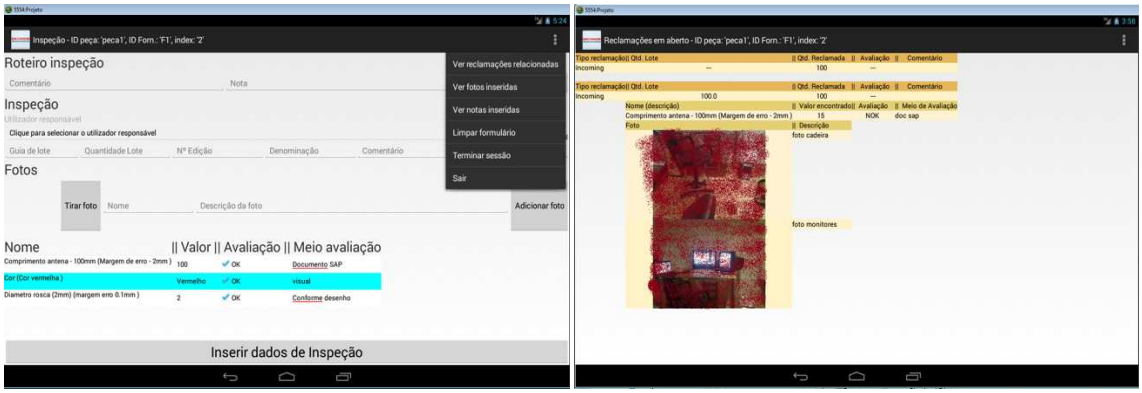

Fig 10: SQMS Mobile App

Discussion and Future Work

With a more global supply chain, it turns more difficult to answer and act on time, when a problem appears. The use of lead technologies as specific software and mobile devices, helps to strengthen the supply chain, making it possible for operator within plant to consult or input richer data (text, audio, photos, videos) from anywhere, using any mobile device. These data stored on a database, can be quickly viewed and analyzed by the management, allowing to take decisions more quickly and in a correct way.

With the SQMS system we expect to improve the internal processes to control the quality of the parts and suppliers. It is also expected to ensure that all quality employees within plant (operators, quality engineers and management quality) follows the quality processes adopted by the company.

In this paper we have presented the SQMS prototype which supports a Supplier Quality Management System of particular OEM Car Manufacturer. The major contribution of this work is the implementation of a platform that automates the several parts of the supplier quality processes in the scenario of a multinational company with several plants across the world.

A prototype was developed to validate the proposed model and architecture. With this prototype we intend to collect data in a scenario of manufacturing environment, to evaluate the real impact that this system can have in the overall efficiency of the supplier quality management process of this OEM automotive industry.

Measurement of Expected Inflation in CEE Countries On the Basis of Consumer Survey Data

Raluca-Elena Pop, The Doctoral School of the Bucharest University of Economic Studies, Bucharest, Romania, pop_ralucaelena@yahoo.com

Abstract

This paper attempts to provide an overview of the different techniques used to convert qualitative assessments from surveys into quantitative data, i.e. the balance statistic, the Carlson-Parkin method and the Pesaran's regression approach. These techniques are then used to determine and compare inflation expectations in Romania, Czech Republic, Poland and Hungary by using data from the European Commission Consumer Survey. The results show an underestimation of actual inflation by the Polish and Czech consumers, while Romanian and Hungarian consumers seem to be more pessimistic, overestimating the actual inflation in a systematic manner.

Keywords: survey data, quantification methods, inflation expectations

Introduction

Expectations regarding future inflation play an important role in the pricing policy of enterprises and in wage negotiations. Also for a monetary policy that is geared towards maintaining a low and stable level of inflation an assessment of how the public forms inflation expectations is of crucial importance as it provides important information about the effectiveness of monetary policy and the credibility of the central bank.

Inflation expectations cannot be observed directly, they have to be derived either from the prices of inflation-indexed financial market instruments or from survey data. In case of the emerging economies the second option is usually preferred due to the still low development level of financial markets in these countries.

There exists a great variety of surveys concerning the expectations of various economic agents regarding the future developments of prices, production, employment etc. One well-survey is the European Commission (EC) Consumer Survey, conducted on a monthly basis and containing questions about the financial and general economic situation, price developments and unemployment. The principle of harmonisation underlying the Commission's survey programme produces a set of comparable data for all Member States. Concerning the price expectations two questions are of interest: one question asks how prices are now compared to 12 months ago and the other aims to find out what the survey participants expect of the future price development. The data from the survey are qualitative in nature, providing a direction of change and not an exact value, and need to be quantified for further analysis.

The focus of this paper is to present different quantification methods of expected inflation on the basis of survey data and to apply these techniques to determine and compare inflation expectations for Romania, Czech Republic, Poland and Hungary using data from EC Consumer Survey. These countries are new European Union member states from Central and Eastern Europe with an explicit inflation targeting monetary policy regime, so inflation expectations and, in particular, how they change over time is of crucial importance for the policymakers.

The paper is related to the contributions of Nardo (2003) and Łyziak (2010). Both papers offer a critical review of the different quantification methods, highlighting the limits of their use in macroeconomic modelling. However Nardo (2003) approach is only theoretical; in contrast, as mentioned, this paper also presents consumers' inflation expectations derived on the basis of qualitative data from the EC Consumer

Survey for Romania, Czech Republic, Poland and Hungary. Moreover, departing from Łyziak (2010), it also provides a comparison between the 4 countries mentioned with respect to perceived and expected inflation, based on the balance statistic indicator, as determined by the EC.

The remainder of the paper is organised as follows: section 2 gives an overview of the data, section 3 describes the methodologies used for converting qualitative survey data into quantitative measures of agents' expectations, while section 4 presents the results. Finally, section 5 concludes.

Data

The Directorate General for Economic and Financial Affairs (DG ECFIN) conducts regular harmonised surveys for different sectors of the economies in the European Union and in the applicant countries. They are addressed to representatives of the industry (manufacturing), services, retail trade and construction sectors, as well as to consumers. Based on the detailed results of the Harmonised Programme, the Commission calculates and publishes a set of monthly composite indicators.

Question number 5 and 6 from the Consumer Survey, which deal with the perceived and the expected inflation, are of interest for the analysis conducted here. *Table 1* shows the exact wording of both questions and the possible answers for the respondents:

Table 1: Questions 5 and 6 from the EC Consumer Survey

Q5: How do you think that consumer prices have developed over the last 12 months? They have…	Q6: By comparison with the past 12 months, how do you expect consumer prices to develop over the next 12 months? They will…
++ Risen a lot (PP^p) + Risen moderately (P^p) = Risen slightly (E^p) - Stayed about the same (M^p) -- Fallen (MM^p) Don't know (N^p)	++ Rise a lot (PP^e) + Rise moderately (P^e) = Rise slightly (E^e) - Stay about the same (M^e) -- Fall (MM^e) Don't know (N^e)

Source: EC Consumer Survey

The countries considered in the analysis are Romania, Czech Republic, Poland and Hungary. These are all new European Union member states with an explicit inflation targeting monetary policy regime. The time span is May 2001-February 2016 for Romania and Poland, January 2001-February 2016 for Czech Republic and February 1993-February 2016 for Hungary respectively (the complete set of available observations for each country).

Figure 1 and *2* illustrate the data, i.e. the weights corresponding to the possible answers for each of the 2 questions extracted from the survey. It is obvious that for the analysed period most of the respondents perceived/expected an increase in prices, although the percentages corresponding to these categories have decreased significantly in the last 2 years as a result of the low inflation environment.

Quantification Techniques of Consumer Inflation Expectations on the Basis of Survey Data

The methods proposed in the literature for converting qualitative survey data into quantitative measures of agents' expectations are essentially three: the balance statistic used by Eurostat, the Carlson-Parkin method and the Pesaran's regression approach.

Balance statistics

Balance statistics offer the easiest way to summarize the responses to survey questions of this kind. They are constructed as the difference between the percentages of respondents giving positive and negative replies.

An example of balance statistic is the one currently used by the European Commission when building composite indicators:

$$BS^{p/e} = \left(PP^{p/e} + 0.5 \cdot P^{p/e}\right) - \left(0.5 \cdot M^{p/e} + MM^{p/e}\right) \quad (1)$$

where $PP^{p/e}$ and $P^{p/e}$ represents the fractions of respondents perceiving/expecting increases in prices of different magnitudes, $M^{p/e}$ represents the fraction of respondents not perceiving/expecting a movement in prices and $MM^{p/e}$ represents the fraction of respondents perceiving/expecting a decrease in prices (see *Table 1*).

Although balance statistics provide a useful and synthetic measure of the opinions expressed in survey, they do not measure expected or perceived inflation directly, being possible that the same distribution of responses to the survey questions to reflect significantly different values of expected/perceived inflation in economies or time periods characterized by high or low inflation (Łyziak (2010)). Also, as shown in Łyziak (2003), an improvement in opinions regarding future price movements, as disclosed by balance statistics, does not necessarily mean that inflation expectations have been reduced but, instead, a higher perceived rate of inflation and, implicitly, higher inflation expectations.

The next two quantification methods were developed in order to overcome these problems and to obtain numerical measures of perceived and expected inflation.

Probability method

The probability method was first employed by Theil (1952) but it was the seminal paper of Carlson and Parkin (1975) that made it popular. It was originally developed to survey questions with three response categories – the so called trichotomous survey. As in this paper data from the EC Consumer Survey is used, the extended version of the probability method due to Batchelor and Orr (1988) that deals with the pentachotomous case will be considered. As there are six possible answers to questions number 5 and 6 from the survey (see *Table 1*), the number of respondents that have chosen the "don't know" option is distributed proportionally between the other response categories.

In the probability method it is assumed that respondents answer survey questions using the median of their own subjective distribution of future inflation, $f_i(\pi_{it}^e/\Omega_t)$, where π_{it}^e represents the time *t* expected future percentage price change of agent *i* for the next 12 months and Ω_t the information set at time *t*. The distribution is segmented by indifference intervals which are considered to be symmetric and equal for all agents: respondents are supposed to report at time *t* an increase/decrease in the price level if the expected future inflation rate is at least θ_t units above/below 0; moreover, they will report a more/less rapid increase in the price level if the expected rate of inflation is at least ε_t units above/below the perceived inflation for the last 12 months, π_{it}^p (*Figure 3*).

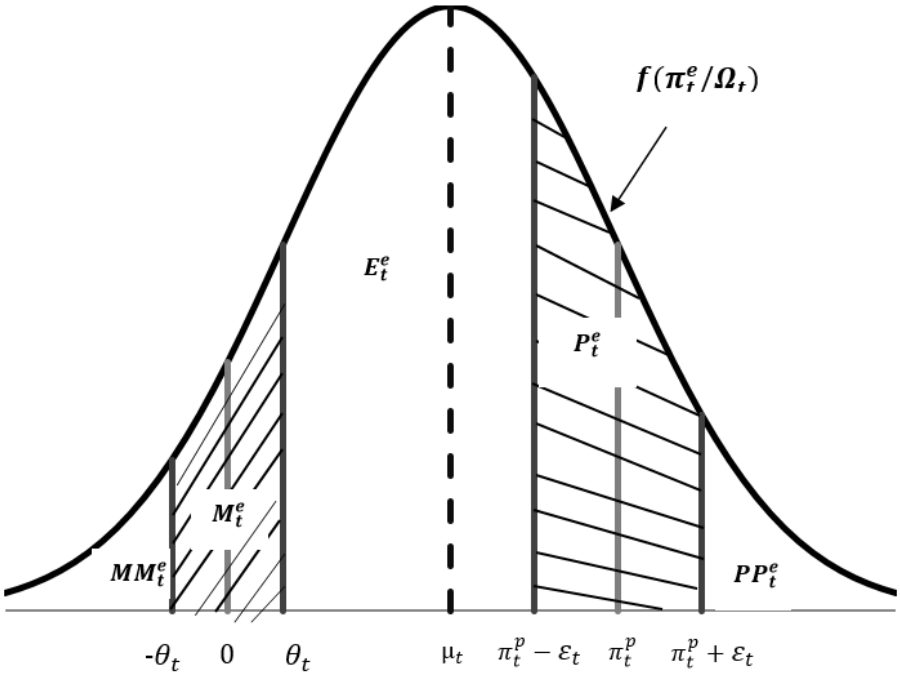

Figure 3. Quantification of pentachotomous survey data for a normal distribution function

If the individual distributions have the same form, are independent across agents and, furthermore, have finite first and second moments, the survey results can be interpreted as a sampling from the joint probability distribution $f(\pi_t^e/\Omega_t)$, with mean $\mu_t = \pi_t^e$, i.e. the expected price change at time *t*, and variance σ_t^2. In this case, the share of respondents replying to each category can be viewed as maximum likelihood estimates of areas under the density function of aggregate inflation expectations:

$$\begin{cases} P(\pi_t^e \le -\theta_t) = \int_{-\infty}^{-\theta_t} f(\pi_t^e/\Omega_t)d\pi_t^e = F(-\theta_t) = MM_t^e & (2) \\ P(-\theta_t \le \pi_t^e \le \theta_t) = \int_{-\theta_t}^{\theta_t} f(\pi_t^e/\Omega_t)d\pi_t^e = F(\theta_t) - F(-\theta_t) = M_t^e & (3) \\ P(\theta_t \le \pi_t^e \le \pi_t^p - \varepsilon_t) = \int_{\theta_t}^{\pi_t^p - \varepsilon_t} f(\pi_t^e/\Omega_t)d\pi_t^e = F(\pi_t^p - \varepsilon_t) - F(\theta_t) = E_t^e & (4) \\ P(\pi_t^p - \varepsilon_t \le \pi_t^e \le \pi_t^p + \varepsilon_t) = \int_{\pi_t^p - \varepsilon_t}^{\pi_t^p + \varepsilon_t} f(\pi_t^e/\Omega_t)d\pi_t^e = F(\pi_t^p + \varepsilon_t) - F(\pi_t^p - \varepsilon_t) = P_t^e & (5) \\ P(\pi_t^e \ge \pi_t^p + \varepsilon_t) = \int_{\pi_t^p + \varepsilon_t}^{\infty} f(\pi_t^e/\Omega_t)d\pi_t^e = 1 - F(\pi_t^p + \varepsilon_t) = PP_t^e & (6) \end{cases}$$

where $F(\cdot)$ represents the cumulative distribution function of $f(\pi_t^e/\Omega_t)$.

Using a standardized variable, the system above can be written as:

$$\frac{-\theta_t - \mu_t}{\sigma_t} = F^{-1}(MM_t^e) = mm_t \quad (7)$$

$$\begin{cases} \dfrac{\theta_t - \mu_t}{\sigma_t} = F^{-1}(MM_t^e + M_t^e) = m_t & (8) \\ \dfrac{\pi_t^p - \varepsilon_t - \mu_t}{\sigma_t} = F^{-1}(MM_t^e + M_t^e + E_t^e) = e_t & (9) \\ \dfrac{\pi_t^p + \varepsilon_t - \mu_t}{\sigma_t} = F^{-1}(MM_t^e + M_t^e + E_t^e + P_t^e) = p_t & (10) \\ PP_t^e + P_t^e + E_t^e + M_t^e + MM_t^e = 1 & (11) \end{cases}$$

Solving for the unknown parameters, μ_t, σ_t, θ_t and ε_t, we obtain:

$$\begin{cases} \mu_t = \pi_t^p \cdot \dfrac{mm_t + m_t}{mm_t + m_t - e_t - p_t} & 12) \\ \sigma_t = -2\pi_t^p \cdot \dfrac{1}{mm_t + m_t - e_t - p_t} & 13) \\ \theta_t = \pi_t^p \cdot \dfrac{mm_t - m_t}{mm_t + m_t - e_t - p_t} & 14) \\ \varepsilon_t = \pi_t^p \cdot \dfrac{e_t - p_t}{mm_t + m_t - e_t - p_t} & 15) \end{cases}$$

The parameters depend on the choice of the distribution function (in order to determine p_t, e_t, m_t and mm_t respectively), as well as on the perceived inflation rate π_t^p, that has a scaling role for the expected inflation rate.

There is no consensus in the literature regarding the actual distribution of expectations, a number of alternatives to normal distribution being considered: the uniform distribution (e.g. Lyziak (2003)), the logistic distribution (e.g. Batchelor and Orr (1988), Nielsen (2003)), the central and non-central t distributions (e.g. Nielsen (2003), Jelea (2013)) and the triangular distribution (e.g. Lyziak (2003)). Without access to individual responses to the survey is it impossible to check the accuracy of the different possible distribution assumptions. However there is evidence in the literature that the chosen distribution makes little difference to the derived expectation series (Nielsen (2003), Batchelor (2006)). In this study the assumption of normality of the underlying aggregate distribution function is chosen, more easily to handle and extensively explored. For this specific case, $F(\cdot)$ represents the cumulative standard normal distribution function.

As far as the scaling parameter is concerned, there are primary two proxies used in the literature: the most recent official inflation rate available to the survey participants and the measure derived on the basis of the survey question concerning past prices. The first proxy implies the rather strict hypothesis that the respondents perceive correctly the officially published inflation rate, so the second method was preferred. The same methodology as the one described above is applied to question number 5, the role of the scaling parameter being replaced by a measure of the moderate rate of inflation which represents the consumers' best guess of the permanent or trend rate of inflation (Batchelor and Orr (1988)). In order to determine the moderate rate of inflation, the Hodrick-Prescott filter is applied to the actual inflation rate for each of the 4 countries considered in the analysis.

The main drawbacks of the probability method concern the fact that it imposes a causal relationship between the current inflation and expected inflation and that the quantified measure is a function of a specific distribution function, although, as mentioned, the chosen distribution seems to make little difference for the derived expectation series. Furthermore, if the distribution is defined over $(-\infty, +\infty)$ the method breaks down if one of the extreme responses of the survey question is chosen by none of the respondents, as, if the value of the aggregate distribution function is zero, the value of the inverse of the normal distribution function approaches minus infinity. This was the case in some periods of the analysed samples, when none of the respondents perceived/expected a decline in prices. The approach used was the

one presented in Sabrowski (2008), more exactly $1/(2n+1)$ was added to the response category that equaled zero, where n represents the number of available observations.

Regression approach

As an alternative to Carlson-Parking method, Pesaran (1984, 1987) developed the regression approach, along the lines suggested by Anderson (1952). This method is based on the assumption that the estimated relationship between current inflation (as measured by official statistics) and its survey perception by respondents holds also between expected inflation and qualitative opinions of respondents concerning future price changes. Thus, in contradiction to probability method, quantitative expectations determined using the regression method are a function of a specific regression model, rather than a function of a specific probability distribution.

There are several models that can be employed in order to approximate the relationship between inflation and the survey data. This paper tests four of them, in line with the study of Łyziak (2010): a simple model based on the balance statistic determined by the European Commission, as well as the models proposed by Anderson (1952), Pesaran (1984, 1987) and Smith and McAleer (1995). *Annex I* provides a complete description of the models employed.

Each model can be summarized by the following equation:

$$\pi_t = \pi_{t+}^{p} \cdot (PP_t^p + P_t^p + E_t^p) - \pi_{t-}^{p} \cdot MM_t^p + \varepsilon_t \quad (16)$$

where the estimated coefficients represents implied average price dynamics perceived by the group of respondents claiming that prices have risen (π_{+}^{p}) and the group of respondents declaring that prices have fallen (π_{-}^{p}) respectively. The structure of the equation, with the official inflation used as the dependent variable and the survey responses as independent ones, imposes unbiasedness of inflation perceptions. Cunningham (1997) argues that in order to obtain unbiased and efficient estimates of the relationship between the survey and official data, the survey data should be the dependent variable because it may contain measurement errors, while it is assumed that the official data is not subject to revision. However, in practice, the differences between this approach and the one suggested by Smith and McAleer (1995) are very small.

According to regression method, the expression above holds not only for realizations, but also for expectations:

$$\pi_t^e = \widehat{\pi_{t+}^{p}} \cdot (PP_t^e + P_t^e + E_t^e) - \widehat{\pi_{t-}^{p}} \cdot MM_t^e \quad (17)$$

It is not mandatory to have a linear relationship between the official inflation and the survey responses as this depends on the way π_{t+}^{p} and π_{t-}^{p} are defined. As pointed out by Nardo (2003), in case of a non-linear relationship between the official inflation and the survey responses - Pesaran's model (1984, 1987), Smith and McAleer model (1995) - *equation (17)* represents only a first approximation of π_t^e, conditional upon qualitative information. Finding π_t^e from a non-linear equation involves also the knowledge of means and variances of qualitative information which is not possible since the individual responses to the survey are not available.

There are several drawbacks to regression approach too. A first one questions the key assumption of the method: there is no clear evidence that people judge the past in the same way as they formulate expectations about the future. Moreover the method is not well suited to work with polychotomous survey, requiring an aggregations of three fractions of respondents perceiving or expecting increases of different magnitudes in prices, this being equivalent to a loss of information. Also it imposes unbiasedness of inflation perceptions, a causal relationship between the current inflation and expected inflation and it does not offer an unique solution for the values of inflation expectations as the reestimation of regression models (for example in order to incorporate new releases of data) leads to different values for the estimated coefficients.

Results

This section presents the results obtained by applying the methodologies described above to the consumer survey data for Romania, Czech Republic, Poland and Hungary.

Balance statistics

Figure 4 shows monthly data for annual CPI inflation as well as the balance statistics of consumers' opinions on perceived and expected inflation determined as presented in *equation (1).* The balance statistic of expected inflation has been shifted forward 12 months, i.e. the actual inflation and the balance statistic of perceived inflation respectively are compared with the expectation for the current period that has been formed 12 months before.

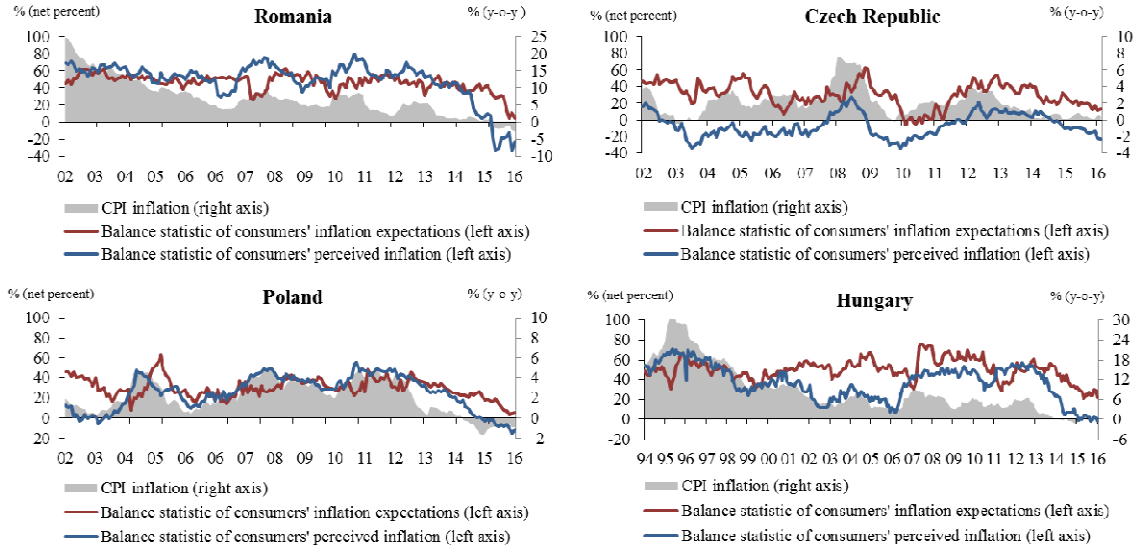

Figure 4: Balance statistics of perceived and expected inflation
Source: EC, INS, CZO, NBP and MNB data

To compare the balance statistics of expected/perceived inflation with the actual inflation the method suggested in Łyziak (2013) is used, i.e. the official CPI inflation is translated into a qualitative measure as follows:

$$\pi_t^{BS} = \begin{cases} 100, if\ \pi_t > \pi_{t-12} \\ 50, if\ \pi_t = \pi_{t-12} \\ 0, if\ 0 < \pi_t < \pi_{t-12} \\ -50, if\ \pi_t = 0 \\ -100, if\ \pi_t < 0 \end{cases} \quad (18)$$

The results are presented in *Table 2*. The average price dynamics expected/perceived as compared to the average of actual inflation suggest that the Polish and Czech consumers form their opinion in an optimistic manner, while Romanian and Hungarian consumers in a pessimistic one. Considering average balance statistics for the period May 2002 – February 2016, for which observations from the survey are available for all the 4 countries analysed, the consumers in Czech Republic seem to be the most optimistic in terms of perceived changes in price level, while Romanians are the most pessimistic. The Czech and Polish consumers reveal the highest degree of optimism when assessing future price changes, while Hungarian consumers the lowest one, followed by Romanians.

Table 2: Average balance statistics of inflation expectations/perceptions and actual inflation

	The complete set of observations			*Common sample (May 2002 - February 2016)*		
Country	Average expected inflation	Average perceived inflation	Average actual inflation	Average expected inflation	Average perceived inflation	Average actual inflation
Romania	46	49	18	46	49	18
Czech Republic	30	-7	36	30	-7	37
Poland	30	25	30	30	25	30
Hungary	50	37	29	51	31	30

Source: Author's calculations based on EC, INS, CZO, NBP and MNB data

In order to compare the consumer capacity to correctly detect the current/future movement in prices, the correlation coefficients between the balance statistics of perceived/expected inflation and the current CPI inflation have been determined. The results are shown in *Table 3*. The consumers from Poland have the highest correlation between the balance statistic of perceived inflation and the current inflation, while the ones from Czech Republic the lowest ones. All the countries present a low degree of correlation between the balance statistic of expected inflation and the current inflation. In Romania the consumers' expectations regarding future inflation follow developments of perceived inflation closely (correlation coefficient of 88% between the two balance statistics): in periods of perceived rising/declining inflation consumers' opinion on expected price changes tend to worsen/improve.

Table 3: Correlation coefficients, common sample (May 2002 – February 2016)

	Correlation coeficient between expected inflation/current inflation	Correlation coeficient between perceived inflation/current inflation	Correlation coeficient between expected inflation/perceived inflation
Romania	44%	63%	**88%**
Czech Republic	23%	53%	34%
Poland	40%	**88%**	55%
Hungary	**55%**	59%	45%

Quantification methods for obtaining numerical measures of perceived and expected inflation

As mentioned in Section 3.2, in case of the probability method the assumption of normality of the underlying aggregate distribution function is employed, more easily to handle and extensively explored. As far as the moderate rate of inflation is concerned, the Hodrick-Prescott filter is applied to the actual inflation rate for each of the four countries considered in the analysis.

Regarding the regression approach, the final version of the estimated equation for each of the economies (*Table 4*) was selected on the basis of a comparison of statistical properties, but also taking into consideration the economic interpretation of the estimated coefficients (e.g. correct signs in accordance with economic theory). For all the 4 countries considered in the analysis an extended version of the model proposed by Smith and McAleer (1995) was preferred.

Table 4: Selected regression models

Country	Model	Estimated equation	$\overline{R^2}$
Romania	Smith and McAleer (1995)	$\pi_t = \frac{0.005 \cdot (PP_t + P_t + E_t) + 7.276 \cdot \pi_{t-1} \cdot MM_t}{1 - 0.982 \cdot (PP_t + P_t + E_t)}$	78%
Czech Republic	Smith and McAleer (1995)	$\pi_t = \frac{0.009 \cdot (PP_t + P_t + E_t) + (3.608 \cdot \pi_{t-1} - 0.030) \cdot MM_t}{1 - 0.867 \cdot (PP_t + P_t + E_t)}$	79%
Poland	Smith and McAleer (1995)	$\pi_t = \frac{0.005 \cdot (PP_t + P_t + E_t) + (14.18 \cdot \pi_{t-1} - 0.227) \cdot MM_t}{1 - 0.898 \cdot (PP_t + P_t + E_t)}$	67%
Hungary	Smith and McAleer (1995)	$\pi_t = \frac{0.009 \cdot (PP_t + P_t + E_t) + (3.52 \cdot \pi_{t-1} - 0.020) \cdot MM_t}{1 - 0.869 \cdot (PP_t + P_t + E_t)}$	92%

Notes: [1] All coefficients are statistically significant at the 5% level of significance. [2] In the estimation the Newey and West (1987) variance-covariance matrix of the coefficients was used for its consistency in the presence of both heteroscedasticity and autocorrelation. [3] The equations are estimated using the complete sets of available observations. Where necessary, dummy variables were added for a better fit of the model.
Source: Author's calculations based on EC, INS, CZO, NBP and MNB data

The series of expected inflation, determined by applying the 2 methodologies and the actually inflation, are represented in *Figure 5*. As the expected inflation concern the next 12 months, the actual inflation is compared with the expectations that have been formed 12 months ago.

Summarizing the results, a couple of points could be made. Firstly, the two proxies of consumers' inflation expectations follow similar tendencies, the only exceptions being the pre-inflation targeting monetary policy regime periods in Romania and Hungary, characterised by a disinflation process. Secondly, expected inflation lags behind the actual inflation, which may have two possible explanations: the expectations are formed in an adaptive manner or the survey participants consider a shorter time span than the twelve months period when answering the questionnaire (Nielsen (2003)). Thirdly, the series of inflation expectations obtained by applying the regression method are more volatile than the ones obtained using the probability method.

The averages of inflation expectations and of actual inflation respectively are reported for the complete sample of available information and for the inflation targeting period (*Table 5*): from the four countries analysed, the Romania was the last one to adopt the inflation targeting (IT) monetary policy regime in August 2005; Czech Republic adopted it in January 1998, Poland in January 1999 and Hungary in June 2001. The results obtained when analysing the balance statistics of expected/perceived inflation are confirmed: the Polish and Czech consumers form their opinion in an optimistic manner, usually underestimating the actual inflation (in the case of Czech consumers the quantification of inflation expectations using the regression approach suggest an overestimation of the actual inflation in the analysed period), while Romanian and Hungarian consumers are more pessimistic, overestimating the actual inflation.

Conclusions

Inflation expectations influence the time path of the economy due to their often substantial impact in the process of agents' decision making. Qualitative survey data that assess the economic agents' expectations regarding future price developments are available. However, for modelling and forecasting purposes this data need to be numerically quantified.

This paper attempts to provide an overview of the different techniques used to convert qualitative assessments into quantitative data, i.e. the balance statistic, the Carlson-Parkin method and the Pesaran's regression approach.

The balance statistic indicator, as calculated by the EC, is used to compare inflation perceptions and expectations in 4 Central and Eastern European countries, i.e. Romania, Czech Republic, Poland and Hungary. Probability and regression methods are used in order to provide numerical estimates of the expectations for the aforementioned countries. The results show an underestimation of actual inflation by

the Polish and Czech consumers, while Romanian and Hungarian consumers seem to be more pessimistic, overestimating the actual inflation in a systematic manner.

ANNEX I: Regression models

Balance statistic regression model:

$\pi_t = \alpha + \beta \cdot BS_t + \varepsilon_t$, where $BS_t = \left(PP_t^p + 0.5 \cdot P_t^p\right) - \left(0.5 \cdot M_t^p + MM_t^p\right)$

Anderson (1952): $\pi_t = \alpha \cdot (PP_t^p + P_t^p + E_t^p) - \beta \cdot MM_t^p + \varepsilon_t$, where $\pi_{t+}^p = \hat{\alpha}$ and $\pi_{t-}^p = -\hat{\beta}$

Pesaran (1984, 1987): $\pi_t = \frac{\alpha \cdot (PP_t^p + P_t^p + E_t^p) - \beta \cdot MM_t^p}{1 - \lambda \cdot (PP_t^p + P_t^p + E_t^p)} + \varepsilon_t$, where $\pi_{t+}^p = \hat{\alpha} + \hat{\lambda} \cdot \pi_t$ and $\pi_{t-}^p = -\hat{\beta}$

Smith, McAleer (1995): $\pi_t = \frac{\alpha \cdot (PP_t^p + P_t^p + E_t^p) - \beta \cdot MM_t^p}{1 - \lambda \cdot (PP_t^p + P_t^p + E_t^p) - v \cdot MM_t^p} + \varepsilon_t$

where $\pi_{t+}^p = \hat{\alpha} + \hat{\lambda} \cdot \pi_t$ and $\pi_{t-}^p = -\hat{\beta} + \hat{v} \cdot \pi_t$

Smith and McAleer (1995), extended version:

$\pi_t = \frac{\alpha \cdot (PP_t^p + P_t^p + E_t^p) - \beta \cdot MM_t^p + (PP_t^p + P_t^p + E_t^p) \cdot \sum_{j=1}^{J} \lambda_j \pi_{t-j} + MM_t^p \cdot \sum_{k=1}^{K} v_k \pi_{t-k}}{1 - \lambda_0 \cdot (PP_t^p + P_t^p + E_t^p) - v_0 \cdot MM_t^p}$

where $\pi_{t+}^p = \hat{\alpha} + \hat{\lambda}_0 \cdot \pi_t + \sum_{j=1}^{J} \hat{\lambda}_j \pi_{t-j}$ and $\pi_{t-}^p = -\hat{\beta} + \hat{v}_0 \cdot \pi_t + \sum_{k=1}^{K} \hat{v}_k \pi_{t-k}$

Notation:

PP^p, P^p and E^p respectively represents the fractions of respondents perceiving increases in prices of different magnitudes

M^p represents the fraction of respondents not perceiving a movement in prices

MM^p represents the fraction of respondents perceiving a decrease in prices

π_t represents actual inflation

π_+^p represents implied average price dynamics perceived by the group of respondents claiming that prices have risen

π_-^p represents implied average price dynamics perceived by the group of respondents claiming that prices have fallen

Consumers and Supermarkets Leaders in Global Value Chain

Abstract

In a Global Value Chain, the changes in organizations are a direct result from the requirements of lead firms. An ideal context to test these affirmations is the Horticultural Value Chain, where producers with close business relationship with large supermarket chains have made a series of strategic organizational changes to respond to consumer demands.

Keywords: Producer, Sustainable Products, Organizational Behaviour, Governance.

Introduction

For the study of Global Value Chain (GVC) it is important not to miss three components mentioned by Kaplinsky and Morris (2001): that the chain is a store of wealth, its operation involves some degree of governance and the existence of various types of chain.

Governance ensures that interactions between firms meet organizational coordinated action, not mere chance. This indicates that the chains are governed when parameters requiring product, process and logistics are closely linked to activities, actors, roles and functions of the nodes that comprise it (Kaplinsky and Morris, 2001). The term, according to Humphrey and Schmitz (2001), is used to emphasize the role of leadership imposed by certain companies over others.

Focused on the exporting horticultural sector in Sinaloa, Mexico which has existed for a century and has an exporting tradition to the United States, this Horticultural Value Chain (HVC) is a product of the interaction between firms responding to coordinated action, where the process and logistics are linked through activities and defined by the actors that make up each of its nodes responsibilities. Between these actors who take the responsibility of increasing the capabilities and quality of the participants involved, have an outstanding role as they exert governance, setting the parameters of that particular market.

The HVC is characterized by being managed by the purchaser, implying that the supermarkets are in charge of governance where capital is its main carrier. The areas of opportunity in order to compete are design and commercialization. And one consideration of major importance in the configuration of the chain is development around perishable goods, which in this case are vegetables.

If it added that supermarket chains respond to the interests of consumers. This is how the working hypothesis was established: *The changes in a GVC of perishable goods are result of the consumer preferences led by supermarket chains.*

Discussion

In the book by Carman, Cook and Sexton (2004) cited from 2000 to nowadays the supermarket chains increased their leading role in American consumer's life, offering a wider range of merchandise, establishing themselves in ample number of cities and adapted themselves to the population's eating habits changes.

Supermarkets got systems that identified consumer's preferences, changes and taste more effectively; this was reflected in their strategies and influence over other stages in the chain. This favored consumers' habits to prefer products that supermarkets offered since these satisfied their requirements, quality needs, quantity and diversity. A producers' readjustment was necessary to satisfy the new market's requirements.

In research study by Reardon, Berdegué and Timmer (2005) stablished demand was not the only factor that justified the fast growth of the supermarkets in the nineties and XXI century. Among others are the detailed commerce liberation and commercial opening by the end of the eighties, accompanied by an organizational adjustment in the mid-nineties that reduced big chains' transaction costs, allowing the establishment of big and small branches in cities in the United States.

Big supermarket chains turned into one of the main distributor's purchasers, which main governance faculty was to transmit market signals to the producers and give support in the improvement of production processes and vegetable quality.The aim is to face consumers with a better knowledge of what it is appropriate to eat.

Supermarket chains have focused in getting to know their clients better, and not only that, but also in offering them high quality products that are good for their health. Based on that experience and knowing they're the most important detailed market at the present time they are aware of their privileged position in the negotiation.

Focusing the consumer on the axis of the economic system producers should expand their knowledge about their characteristics, tastes and preferences. Brambilia (2006) mentioned in order to define what, how and when to produce, borders disappear leaving the import and export flow products that meet consumer demand.

Knowledge about consumer must focus on:

- Identify the product it will give greater value
- The most appropriate presentation
- Establishments to buy more frequently
- Frequency of purchase
- Consumer preference
- Habits and income

As a pilot, observation method was used in some supermarket chains and wholesalers located in Sinaloa (Walmart, Ley, MZ, Comercial Mexicana, Sam's Club, Costco, City Club), itwas possible to detect when the consumers buy vegetables:

- The highest percentage of consumers select for theappearance, assuming that the product has quality
- Most of them buy the products on offer
- A minority buy organic products
- During the morning and those who buy organic products use sportswear
- About 60% of customers are women and 40% men
- If a consumer wants to know the diversity of vegetable (for example, organic, hydroponic or other) employees lack information

- There is no information that allows consumers to try new products or grown with healthy methods
- Most consumers are adults

In survey of 400 customers:

- 89 percent are buying vegetables at the supermarket
- 11 percent in other establishments (wholesale stores or other retailers)
- 23.5 percent consume organic products every day

With consumers more informed and aware of what they eat. Supermarket chains have to know their costumers profoundly in order to offer the most suitable selection of products that also fulfill their health requirements. Especially when it tends to sustainable products.

Conclusion and Implications

There are no precise records on the motivations, tastes and preferences by which consumers opt for horticultural products. However, attributes related to quality are considered determinants. Which leads to supermarket chains to set high standards when selecting their suppliers. Knowledge that allows them to establish leadership in the HVC.

Supermarkets then define quality to producers that require and demand specific presentations, safety and excellent appearance. Therefore, consumers have as preferred supplier to chains, which are guaranteed quality.

It should be understood, trading vegetables involves a consumer who has become an active player, concerned about their food, who exercises more frequently and reporting on the implications of the consumption of unhealthy foods. Therefore, the implications of the research are to understand consumer preferences, the role of supermarket chains as experts in the market and identify changes in the growing demand for healthy products (sustainable products).

Formal Verification of Business Processes using Model Checking

Florin Stoica, "Lucian Blaga" University, Sibiu, Romania, florin.stoica@ulbsibiu.ro

Abstract

The solution against the changing business environment is construction of flexible business processes in order to be aligned with actual business needs and requirements. The reliability of a business process can be increased through modelling of the process before the implementation of code, followed by the verification of its correctness. Verification of a business process involves checking whether the process in question behaves as it was designed to behave. Model checking is a technology widely used for the automated system verification and represents a technique for verifying that finite state systems satisfy specifications expressed in the language of temporal logics. Formal verification of business process models aims checking for process correctness and business compliance. This paper presents a suitable approach for automatic verification of a business process using Alternating-time Temporal Logic (ATL). In development of a user-friendly supporting tool, we will use our original ATL model checker.

Keywords: Business Process, Formal Verification, ATL model checking

1 Introduction

Languages such as UML, Java, C++, C# and programming paradigms like Object Oriented Programming (OOP), while necessary to implement IT solutions, are not intended for communication with business people, and so do not facilitate the necessary connection they need to have.

Business Process Management (BPM) methodology is a paradigm which is focused on business processes, under the assumption that a business will be as efficient as the processes that it runs. A Business Process Management Suite (BPMS) represents a technology platform through which can be implemented BPM. BPMS allows implementation of business processes quickly and provide the agility and speed required in order to adapt to the changes occurring in the business environment. A BPMS platform provides a single integrated environment tool for the development and deployment of business processes through its enabling technologies: BPMN (Business Process Modelling Notation) modelling tools, process engine, business rules engine, orchestration engine, analysis and simulation tools and an integration environment to connect processes with applications and external sources.

Almost everything we do with software development can be seen as processes. To develop a process-based application of any type, we generally respect some or all of the following steps, using different features provided by BPMS platforms (Bonitasoft documentation, 2016):

- Model the process;
- Define process data;
- Define forms;
- Define business rules;
- Integration with other Information Systems;
- Define users (actors);
- Simulation;
- Implementation;
- Monitoring and reporting.

In this paper we will use Bonita as BPMS platform. It offers the advantage of being fully process oriented and provides all the tools necessary to model, implement, manage and control the business process life cycle, allowing the development of a process-based application fast and efficiently.

Because testing and simulation can give us only confidence in the implementation of a software system, but cannot prove that all bugs have been found, we will use a formal method, namely model checking, for detecting and eliminating bugs in the design of a business process.

Design validation involves checking whether a system design satisfies the system requirements. Model checking is a technology widely used for the automated system verification and represents a technique for verifying that finite state systems satisfy specifications expressed in the language of temporal logics.

Alur, Henzinger and Kupferman (2002) introduced Alternating-time Temporal Logic (ATL), a more general variety of temporal logic, suitable for specifying requirements of multi-agent systems. ATL is also widely used to reason about strategies in multiplayer games. The semantics of ATL is formalized by defining games such that the satisfaction of an ATL formula corresponds to the existence of a winning strategy.

Using the approach presented in this paper, the reliability of a process-based application can be increased through the validation and verification of its Business Processes modelled using the BPMN 2.0 semi-formal notation in the first step of the development life cycle.

Starting from a model of a process given in BPMN 2.0 we provide a mapping to a formal specification in the form of concurrent game structures. This transformation makes possible formal and automatic verification of desired quality requirements of a given business process.

Using the Java version of our ATL Library, the standard methods of the Bonita BPM Engine have been overwritten such that building of the ATL model to be done in parallel with the definition of the business process. Thus our method is also suitable for business processes that were constructed directly using BPMN engine API calls.

The paper is organized as follows. In the next section, we provide some background material related to Alternating-time Temporal Logic. We present the definition of the concurrent game structure, the ATL syntax, the ATL semantics and a short description of our ATL model checker. In Section 3, we describe the formal model of a business process, the ATL model used to define the formal mappings and the visual model (using BPMN) of the formal verification approach we propose. A case study is presented in Section 4. We report related works in Section 5. Finally, are presented some conclusions and opportunities for future investigations in Section 6.

2 Alternating-Time Temporal Logic

The ATL logic was designed for specifying requirements of open systems. An open system interacts with its environment and its behaviour depends on the state of the system as well as the behaviour of the environment.

The model checking problem for ATL is to determine whether a given model satisfies a given ATL formula. ATL defines “cooperation modalities” of the form <<A>> φ, where A is a group of agents. The intended interpretation of the ATL formula <<A>> φ is that the agents A can cooperate to ensure that φ holds (equivalently, that A have a winning strategy for φ) (Kacprzak and Penczek, 2005).

ATL has been implemented in several tools for the analysis of open systems. In a paper by Alur et al. (1998) is presented a verification environment called MOCHA for the modular verification of heterogeneous systems. The input language of MOCHA is a machine readable variant of reactive modules. Reactive modules provide a semantic glue that allows the formal embedding and interaction of components with different characteristics (Alur and Henzinger, 1996).

In a paper by Lomuscio and Raimondi (2006) is described MCMAS, a symbolic model checker specifically tailored to agent-based specifications and scenarios. MCMAS takes a dedicated programming language called ISPL (Interpreted Systems Programming Language) as model input language.

Specifications of our original ATL model checker can be found in the paper by Stoica (2015). We will use our tool in this paper because it allows a transparent building of the ATL model at runtime, using the native language of the BPMN engine (Java).

In the following we will present the computational model used by ATL to describe compositions of open systems, called Concurrent Game Structure (CGS).

2.1 The Concurrent Game Structure

A concurrent game structure (CGS) is defined as a tuple $S=\langle \Lambda, Q, \Gamma, \gamma, M, d, \delta \rangle$ with the following components:

- a nonempty finite set of all agents $\Lambda = \{1, \ldots, k\}$;
- Q denotes the finite set of *states* ;
- Γ denotes the finite set of *propositions* (or *observables*);
- γ: $Q \rightarrow 2^{\Gamma}$ is called the *labelling* (or *observation*) function, defined as follows: for each state $q \in Q$, $\gamma(q) \subseteq \Gamma$ is the set of propositions *true* at q;
- M represents a nonempty finite set of moves;
- the *alternative moves* function d: $\Lambda \times Q \rightarrow 2^{M}$ associates for each player $a \in \{1,\ldots,k\}$ and each state $q \in Q$ the set of available moves of agent a at state q. In the following, the set $d(a,q)$ will be denoted by $d_a(q)$. For each state $q \in Q$, a tuple $\langle j_1,\ldots,j_k \rangle$ such that $j_a \in d_a(q)$ for each player $a \in \Lambda$, represents a *move vector* at q.
- the transition function $\delta(q,\langle j_1,\ldots,j_k \rangle)$, associates to each state $q \in Q$ and each move vector $\langle j_1,\ldots,j_k \rangle$ at q the state that results from state q if every player $a \in \{1,\ldots,k\}$ chooses move j_a.

A *computation* of S is an infinite sequence $\lambda = q_0, q_1, \ldots$ such that q_{i+1} is the successor of q_i, $\forall i \geq 0$. A *q-computation* is a computation starting at state q. For a computation λ and a position $i \geq 0$, we denote by $\lambda[i]$, $\lambda[0,i]$, and $\lambda[i,\infty]$ the i-th state of λ, the finite prefix $q_0, q_1,\ldots,q_i$ of λ, and the infinite suffix $q_i, q_{i+1} \ldots$ of λ, respectively (Alur, Henzinger and Kupferman, 2002).

In the paper which introduced ATL, the moves of agents are encoded by natural numbers (Alur, Henzinger and Kupferman, 2002). We have extended the original definition of concurrent game structure allowing that moves to be encoded by abstract objects of a set M. This will help us to define mappings between BPMN and CGS.

2.2 ATL Syntax

We denote by $F_S(A)$ the set of all well-formed ATL formulae defined over a concurrent game structure S and a set of agents $A \subseteq \Lambda$. Each formula from $F_S(A)$ can be obtained using recursively the following rules:

(R1) if $p \in \Gamma$ then $p \in \mathcal{F}_S(\mathcal{A})$;
(R2) if $\{\varphi, \varphi_1, \varphi_2\} \subseteq \mathcal{F}_S(\mathcal{A})$ then $\{\neg \varphi, \varphi_1 \vee \varphi_2\} \subseteq \mathcal{F}_S(\mathcal{A})$;
(R3) if $\{\varphi, \varphi_1, \varphi_2\} \subseteq \mathcal{F}_S(\mathcal{A})$ then $\{\langle\langle \mathcal{A} \rangle\rangle \circ \varphi, \langle\langle \mathcal{A} \rangle\rangle \Box \varphi, \langle\langle \mathcal{A} \rangle\rangle \varphi_1 \, U \, \varphi_2\} \subseteq \mathcal{F}_S(\mathcal{A})$.

The path quantifiers in the ATL logic are parameterized by sets of players from Λ. The operator $\langle\langle \, \rangle\rangle$ is a path quantifier, and $\circ$ ('next'), $\Box$ ('always'), $\Diamond$ ('future') and U ('until') are temporal operators. A formula $\langle\langle A \rangle\rangle \varphi$ expresses that the team A has a collective strategy to enforce φ. Boolean connectives can be defined from $\neg$ and $\vee$ in the usual way. The ATL formula $\langle\langle A \rangle\rangle \Diamond \varphi$ is equivalent with $\langle\langle A \rangle\rangle$ *true* U φ.

2.3 ATL Semantics

Consider a game structure $S=\langle \Lambda,Q,\Gamma,\gamma,M,d,\delta\rangle$ with $\Lambda=\{1,\ldots,k\}$ the set of players. We denote by D_a the set of available moves of agent a within the game structure S.

A *strategy* for player $a\in\Lambda$ is a function f_a: $Q^+\rightarrow D_a$ that maps every nonempty finite state sequence $\lambda=q_0q_1\ldots q_n$, $n\geq 0$, to a move of agent a denoted by $f_a(\lambda)\in D_a\subseteq M$. Thus, the strategy f_a determines for every finite prefix λ of a computation a move $f_a(\lambda)$ for player a in the last state of □.

Given a set $A\subseteq\{1,\ldots,k\}$ of players, the set of all strategies of agents from A is denoted by $F_A=\{ f_a \mid a\in A \}$. The *outcome* of F_A is defined as $out_{F_{\mathcal{A}}}: Q\rightarrow P(Q^+)$, where $out_{F_{\mathcal{A}}}(q)$ represents *q-computations* that the players from A are enforcing when they follow the strategies from F_A and $P(Q^+)$ represents the set of parts of the set Q^+. In the following, for $out_{F_{\mathcal{A}}}(q)$ we will use the notation $out(q,F_{\mathcal{A}})$. A computation $\lambda=q_0,q_1,q_2,\ldots$ is in $out(q,F_{\mathcal{A}})$ if $q_0=q$ and for all positions $i\geq 0$, there is a move vector $\langle j_1,\ldots,j_k\rangle$ at state q_i such that (Alur, Henzinger and Kupferman, 2002):

- $j_a=f_a(\lambda[0,i])$ for all players $a\in\mathcal{A}$, and
- $\delta(q_i, <j_1,\ldots,j_k>)= q_{i+1}$.

For a game structure S, we write $q\models\varphi$ to indicate that the formula φ is satisfied in the state q of the structure S. For each state q of S, the satisfaction relation $\models$ is defined inductively as follows:

- for $p\in\Gamma$, $q\models p \Leftrightarrow p\in\gamma(q)$
- $q\models\neg\varphi \Leftrightarrow q\not\models\varphi$
- $q\models\varphi_1\vee\varphi_2 \Leftrightarrow q\models\varphi_1$ or $q\models\varphi_2$
- $q\models\langle\langle\mathcal{A}\rangle\rangle\circ\varphi \Leftrightarrow$ there exists a set $F_{\mathcal{A}}$ of strategies, such that for all computations $\lambda\in out(q, F_{\mathcal{A}})$, we have $\lambda[1]\models\varphi$ (the formula φ is satisfied in the successor of q within computation λ).
- $q\models\langle\langle\mathcal{A}\rangle\rangle\Box\varphi \Leftrightarrow$ there exists a set $F_{\mathcal{A}}$ of strategies, such that for all computations $\lambda\in out(q, F_{\mathcal{A}})$, and all positions $i\geq 0$, we have $\lambda[i]\models\varphi$ (the formula φ is satisfied in all states of computation λ).
- $q\models\langle\langle\mathcal{A}\rangle\rangle\varphi_1 U\varphi_2 \Leftrightarrow$ there exists a set $F_{\mathcal{A}}$ of strategies, such that for all computations $\lambda\in out(q, F_{\mathcal{A}})$, there exists a position $i\geq 0$ such that $\lambda[i]\models\varphi_2$ and for all positions $0\leq j<i$, we have $\lambda[j]\models\varphi_1$.

2.4 Implementation of an ATL Model Checker

Our ATL model checker tool contains the following packages:

- ATL Compiler – the core of our tool, is an algebraic compiler (Cacovean, 2009), embedded into a Web Service (ATL Checker) (Stoica and Boian, 2012);
- ATL Designer – the GUI client application used for interactive construction of the ATL models as directed multi-graphs;
- ATL Library – used for development of custom applications with large ATL models. Versions of this library are provided for C# and Java.

For □ ATL operator we use in our tool the # symbol. Also, we denote the ◊ ATL operator with ~ symbol and the ○ operator is replaced by @ symbol. The software can be downloaded from http://use-it.ro (binaries and examples of use).

For a better understanding of the ATL model checking process, in Fig. 1 is represented the Use Case Diagram of our model checker. The Web service will receive from a client the XML representation of an ATL model and an ATL formula. After deserialization, the original form of the ATL model is passed to the ATL compiler. For a syntactically correct formula, the compiler will return as result the set of states in which the formula is satisfied. If the ATL formula is not valid, the Web service will return a message describing the error.

In this paper we are using the ATL Library to build and to verify the ATL model of a business process which was defined using methods of the *ProcessDefinitionBuilder* class of the Bonita BPMN engine, but our methodology can be adapted to any BPMN engine, using its API for defining executable business processes.

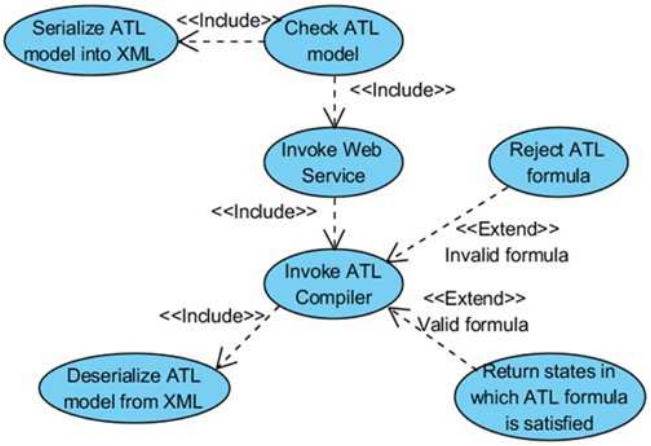

Fig. 1: The Use Case Diagram of the ATL model checker

Our experimental evaluation has been conducted within our ATL model checker (Stoica, 2015). Exploring the business process model, branching occurs only with reference to exclusive gateway. This gives us the possibility to explore alternative paths and avoid state explosion phenomenon (Falcioni et al., 2012).

3 Verification of Business Processes using ATL model checking

3.1 A Formal Model of the Business Process

A business process occurs when people interact in a coordinated manner to achieve a common business goal. Business Process Modelling Notation (BPMN) is a standard that allows the building a visual model which expresses a workflow's business requirements graphically.

In the following we present a formal model for a business process depicted using a BPMN Diagram composed by three basic categories of elements: Flow Objects, Connecting Objects and Swimlanes, which are described in the Fig. 2. Flow Objects are the main graphical elements to define the behaviour of a Business Process. There are three types of Flow Objects: Tasks, Gateways and Events (BPMN 2.0 reference, 2016).

A Pool contains a single, complete process. Swimlanes are used to help organize the process, to organize and categorize tasks. Because lanes are purely for organizational clarity, we do not include them in our formal model of the business process. We will consider in the following three types of Connecting Objects:

1. *Uncontrolled flow*: refers to flow that is not affected by any conditions or does not pass through a Gateway;
2. *Conditional flow*: has a condition expression that is evaluated at runtime to determine whether or not the flow will be used;
3. *Default flow*: this flow will be used only if all the other outgoing conditional flow is not true at runtime and will have a diagonal slash that will be added to the beginning of the line.

A Business Process is a tuple $BP = (F, C, \Pi, \pi, s_e, E_F, ce, \delta_{BP})$ where:

- $F = T \cup G \cup E$ is the set of Flow Objects, composed by Tasks (T), Gateways (G) and Events (E).
- $C = C_U \cup C_C \cup C_D$ denotes the set of Connecting Objects, composed by Uncontrolled flows (C_U), Conditional flows (C_C) and Default flows (C_D).
- Π denotes the finite set of names of Flow Objects (F) and Connecting Objects (C).
- π: $F \cup C \rightarrow \Pi \cup \{none, default\}$ is called the *labelling* function, defined as follows: for each business process diagram object $o \in F \cup C$, $\pi(o) \in \Pi$ is the *name* of the object o. Uncontrolled flows and Default flows will have assigned the name *none* and respectively *default*.
- s_e is an element of the set of events E, denoting the *start event*.
- $E_F \subseteq E$ is the set of *end events*.
- The function ce: $C \rightarrow \Pi \cup \{none, default\}$ assigns to each connecting object from C its *condition expression*. For simplicity, we will define ce as restriction of π to C:
  $ce = \pi_{|C} : C \rightarrow \Pi \cup \{none, default\}$ where:

$$ce(c) = \begin{cases} none \text{ if } c \in C_U \\ default \text{ if } c \in C_D \\ \pi(c) \text{ if } c \in C_C \end{cases}$$

- The transition function $\delta_{BP}(f_o, c_o)$, associates to each flow object $f_o \in F$ and each outgoing connecting object $c_o \in C$ the flow object connected to f_o by c_o.

Flow Objects	
Tasks Gateways Start Events Int. Events End Events	Tasks are performed in the process by users or by automation (service tasks). Gateways are used to join or separate process flow. Events are used to start or end a process and to manage specific actions during a workflow. An event is something that "happens" during the course of a business process.
Connecting Objects	
Flow	The sequence flows are used to show how the workflow evolves.
Swimlanes	
Swimlanes	A pool contains a single process. Lanes are used to organize and categorize activities.

Fig. 2: BPMN graphical objects used in Business Process Diagrams

This model will help us to elaborate the mapping rules between ATL and BPMN concepts.

3.2 ATL Model of the Business Process

For a Business Process model defined in section 3.1, the equivalent concurrent game structure $S=\langle \Lambda, Q, \Gamma, \gamma, M, d, \delta \rangle$ is defined as follows:

– There is only one agent, i.e. $\Lambda = \{1\}$;
– The set of states is $Q = F$;
– The finite set of *propositions* is defined by $\Gamma = \pi_{|F}(F)$;

– The *labelling* function γ: $Q \rightarrow 2^{\Gamma}$ is defined as follows:

$$\gamma(q) = \pi_{|F}(q)$$

– The nonempty finite set of moves *M* contains all *condition expressions*, i.e.:

$$M = \bigcup_{c \in C} ce(c)$$

– The *alternative moves* function $d{:}\Lambda \times Q \rightarrow 2^{M}$ is defined by $d(1,q) = \bigcup_{c \in C_q} ce(c) \forall q \in Q$ where C_q represents the set of connecting objects outgoing from *q*.

– The transition function □ is defines as follows:

$$\delta(q, < j >) = \delta_{BP}(q, j) \forall q \in Q \, and \, \forall \, j \in \bigcup_{c \in C_q} ce(c)$$

3.3 Formal Verification of a Business Process

Automated verification of a Business Process (BP) by ATL model checking is the formal process through which a given specification expressed by an ATL formula and representing a desired behavioural property is verified to hold for the ATL model of that BP. Using proposed approach can be discovered conformance failures for a given BP (discrepancies between actual and expected results) which may indicate any of the following: implementation bug, modelling error, specification error or design error of the verified BP.

For a given BP, its formal verification using the ATL model checking is done in two steps:

1. For the beginning, the corresponding ATL model is constructed following rules described in section 3.2;
2. Then, a given specification (ATL formula) representing a desired behavioural property is verified to hold for the model obtained at step 1.

The entire process of verification of a BP using ATL model checking is presented in the following process diagram:

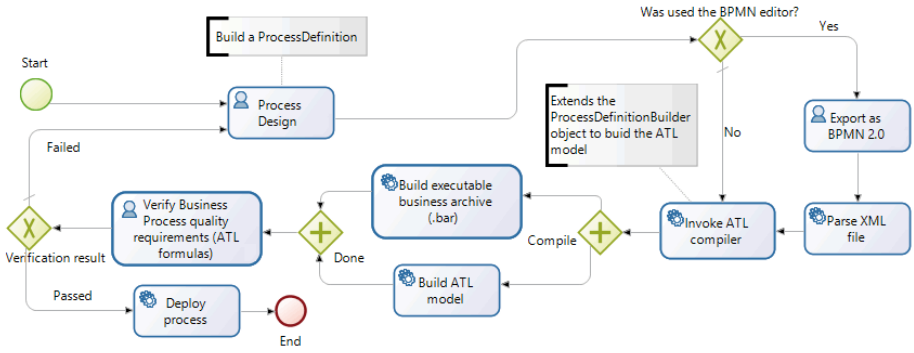

Fig. 3: Formal verification of a BP using ATL model checking

The core of our ATL model checker is the ATL compiler which translates a formula φ of a given ATL model to set of nodes over which formula φ is satisfied. The original implementation of the model checking algorithm is based on Relational Algebra expressions translated into SQL queries (Stoica, 2015). The broad goal of our research was to develop a reliable, easy to maintain, scalable model checker tool to improve applicability of ATL model checking in design of general-purpose computer software.

In order to use the ATL model checker in verification of business processes, we have extended the ATL compiler with a component that addresses the parsing of a process definition provided by *ProcessDefinitionBuilder* class of the BPM Engine. Our parser uses the Java version of the ATL Library –

a component of our ATL model checker, used for development of custom applications with large ATL models – to enhance the functionality of the standard methods of *ProcessDefinitionBuilder*, adding the code necessary to build in a transparent manner the ATL model of the verified business process, using mappings between formal models as they were defined in sections 3.1 and 3.2. These mappings are carried out by the classes and methods presented in Table 1 (ignoring the call parameters):

Table 1: Overwriting the methods of BPM engine to build transparently the ATL model

BPM engine API	ATL model checker (ATL Library)
ProcessDefinitionBuilder	ATLGraphModel
addStartEvent, addUserTask, addAutomaticTask, addGateway, addEndEvent, etc.	addNode
addTransition, addDefaultTransition, etc.	addEdge

4 A Case Study: Approval Process for an Employee Vacation

In the following we will consider a simplified process for requesting approval of vacation in a company. A vacation request submitted by an employee will be approved or rejected by the HR manager. However the HR manager may request other submission, thus delaying the final decision. The equivalent diagram in Bonita BPM Studio is as follows:

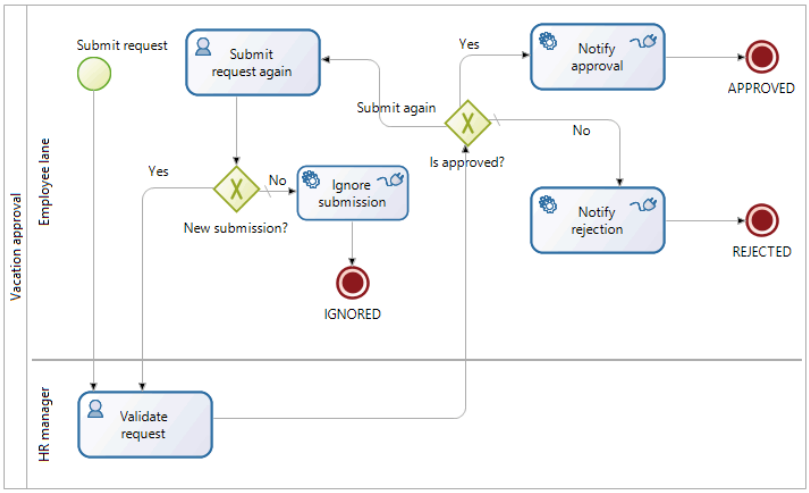

Fig. 4: The BPMN 2.0 specification of the approval process

According to the process design, an email notification is sent to an employee when the HR manager has approved the request or when the request has refused. The email notification will be sent to the employee who has submitted the request. For a request identical with one previously sent, the employee will receive the message „*Vacation request already submitted!*"

After building of the executable model and deployment of the business process application, users will use the Bonita BPM Portal to view tasks and take actions. Our example application contains web forms (created with Bonita BPM Studio) which are displayed to the end users when they trigger the creation of the process instance or perform their assigned tasks.

In the Fig. 5 is presented the form to be used by all employees, and which gathers all the required information to submit a vacation request and respectively the form to be used by the HR manager to review the requests submitted by the employees.

Using the ATL model, the analyst can establish the quality properties of the Business Process (BP) to be checked. The properties to be verified are described as goals to reach or conditions that BP states have to satisfy and are expressed by ATL formulas. The ATL model checker tool automatically assesses the quality of a designed BP with respect to defined quality requirements. In case some properties are violated, the BP designer will be asked to review the process model.

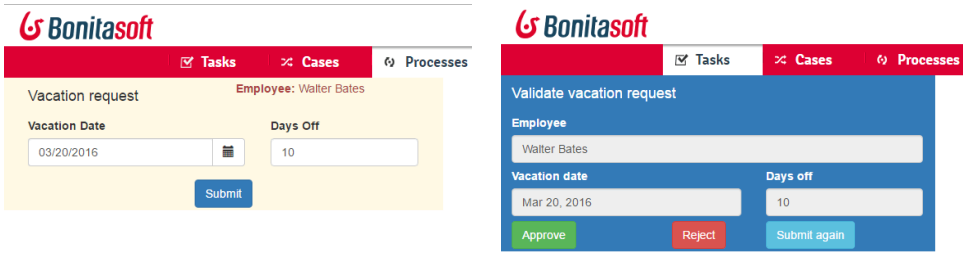

Fig. 5: Web forms provided by business process application

The ATL model of the business process, built by our tool described in section 2.4 and loaded in ATL Designer is presented in the Fig. 6.

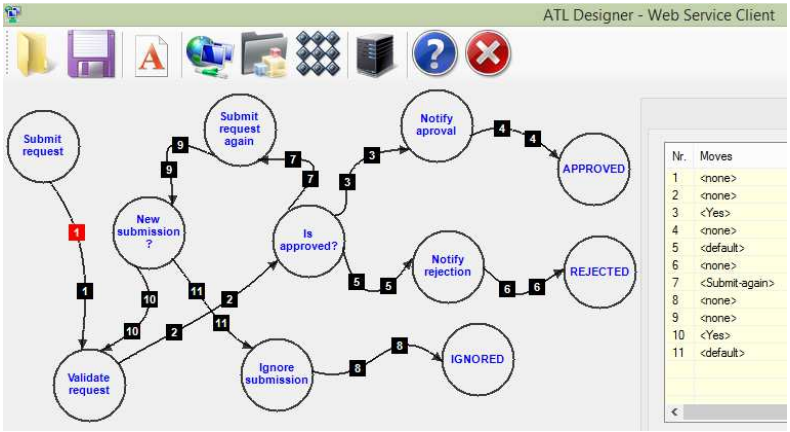

Fig. 6: The ATL model of the business process

The model checking problem for ATL is to determine whether a given BP with its structure described in a mathematical model (a concurrent game structure) satisfies a given ATL formula.

The model checker takes as input the concurrent game structure of the BP and the ATL formula φ (the property to be checked), and provides as output $Q'=\{q \in Q \mid q \vDash \varphi\}$ – the set of states where the formula φ is satisfied. Using this approach can be detected error states (the states of the model where the ATL formula does not hold) and thus the design of the verified BP can be corrected / improved.

For the BP analysed in this section, a natural requirement is that each request submitted by an employee to be rejected or approved and thus the employee to be notified of the result of his request. The ATL formula checked is:

<<A>>~ (APPROVED or REJECTED)

As we can see from the Fig. 7, the desired behavioural property expressed by ATL formula does not hold for the entire model. The formula does not hold in states 8 and 9. This can lead to unexpected results at runtime.

Indeed, if upon the request received from the HR manager to reformulate its request, the employee resends an identical request to previous one, its submission will be ignored (probably assuming that it was already analysed).

To correct this error, a constraint must be enforced at the task "*Submit request again*" to ensure that the employee always will send a request different from the previous one.

The formal verification of a BP using ATL model checking is accomplished using the prototype tool presented in Fig. 8.

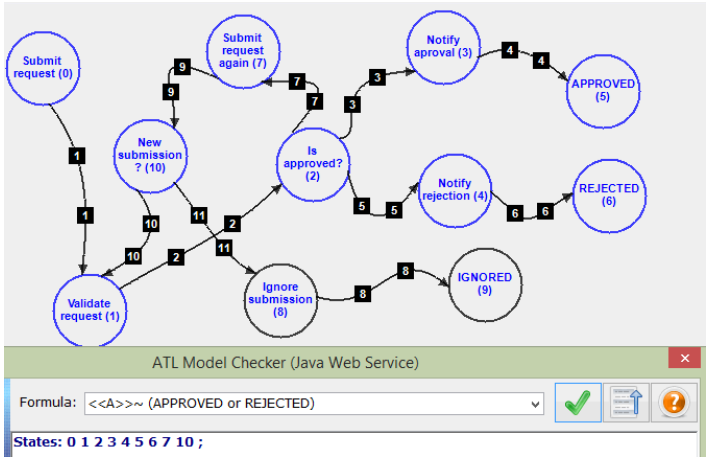

Fig. 7: Verification of the BP model

The developed tool uses the following APIs:

- BPM Engine API and ATL Library to build the process definition and its corresponding ATL model and also to build and deploy the executable business process (.bar file);
- Web REST API for access to all Bonita BPM objects (processes, tasks, users, etc.);
- ATL Library for checking the ATL model of BP.

Our tool are using JSON data-interchange format for communication with BPM Engine and to convert the output provided by ATL model checker.

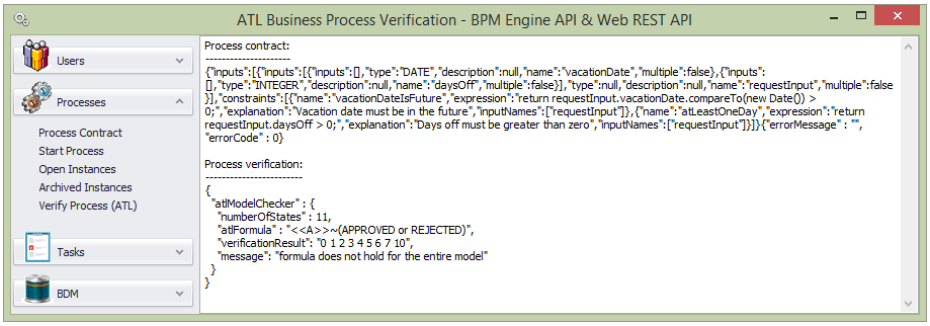

Fig. 8: The tool for verification of BP using ATL model checking

5 Related Works

Formal verification of business process models is of interest to a number of application areas, including checking for process correctness (verifying properties such as reachability and termination) and for business compliance.

The research paper by Morimoto (2008) provides a survey on BP verification techniques and an interesting classification of approaches for formally modelling BP: automata, Petri Nets, Process Algebras. A very detailed survey is presented in a research study by Groefsema and Bucur (2013), where are classified the verification techniques and are reviewed the frameworks used in the business process model checking. In the paper by Dijkman, Dumas and Ouyang (2010) is proposed a mapping from BPMN to a formal language, namely Petri Nets to enable the static analysis of BPMN models. The formalisation also led to the identification of deficiencies in the BPMN standard specification.

An approach related to the definition of a mapping from BPMN to a formal notation is discussed by Wong and Gibbons (2011). The authors demonstrate how process algebras such as Communicating Sequential Processes (CSP) can be applied to model complex workflow systems and have provided a formal semantic for BPMN elements in CSP processes using Z notation (Wong and Gibbons, 2008).

In a research paper by Polini, Polzonetti and Re (2012) is described an approach for BP design and verification in the field of public administration. In order to enable automatic verification of BP, the different BPMN constructs were mapped to the input formalism accepted by the PAT model checker and quality requirements have been encoded as temporal properties in Linear Temporal Logic (LTL). More exactly, a BPMN specification is mapped to a Communication Sequential Process (CSP).

In the paper by Falcioni et al. (2012) is proposed a BP verification technique based on an optimized unfolding algorithm taking advantage of the specific BPMN 2.0 semantic.

In a research study by Corradini et al. (2010) the BP verification is applied in the domain of e-Government Service Delivery. The authors introduce a methodology and a tool to formally and automatically assess the quality of a designed business process with respect to defined quality requirements. The tool integrate PAT as model checker and uses CSP formalism as input language.

Software Architecture Description Language (SADL) and a CTL model checker were used for formal verification of domain-specific applications (Cacovean, 2010). The CTL model checking was also used in a research paper by Cacovean et al. (2009) for determination of the behaviour of actors involved in capital market.

The ATL model checker used in this paper was successfully used in verification of JADE agents with Finite State Machine (FSM) behaviours (Stoica and Boian, 2015).

To the best of our knowledge the approach we present is the first attempt based on Alternating-Time Temporal Logic that tries to provide an easy to use tool for verification of process-based applications.

6 Conclusions and Future Work

Business Process Modelling Notation (BPMN) intends to bridge the gap between business process design and implementation of enterprise information systems such that both the business and technical sides of the organization can share a common language, with significant benefits in the deployment of new and more flexible applications. Although Business Process Modelling (BPM) is effective for the development of process-based applications, a diagram modelled with the BPMN notation may have various interpretations and lacks strictness. Thus, before utilizing BPM, we must define strict semantics of the models and verify formally the business process diagrams.

In this paper we presented an approach for detecting conformance failures of complex Business Processes (BP) modelled using BPMN 2.0 as early as possible and in any case before the deployment of the BP in production. Our formal verification technique of business process diagrams is intended for design-time verification. The verification of the BP using our approach helped in identifying dangerous traces, aiming the business compliance of the BP but it is also suitable for verifying basic properties such as reachability and termination.

The current implementation of the approach raise the reliability of business process diagrams performing automatic check if a business process model satisfies the quality requirements encoded as temporal properties in Alternating-time Temporal Logic. In the future we intend to improve our tool by adding support for complex branching features of the modelling formalism (e.g., to support parallel gates and execution loops). At the same time we will consider the runtime verification issues of BP. Other extension of the ATL model can be achieved by inclusion in the set of agents of all actors defined at the pool level.

Abstract

The aim of the paper is to conceptualize the construct 'endogenous evolutivity' as well as to refer that to the organizational adaptiveness phenomenon. The method that has been used is deepened literature study. We have envisaged that high endogenous evolutivity comprehended as organizational routines' embeddedness would rather hinder organizational adaptiveness in terms of fluidity, strategic flexibility, and non-financial performance.

Keywords: adaptiveness, endogenous evolutivity, routines' embeddedness, organizational routines.

Introduction

It has been envisaged that endogenous evolutivity as organizational routines' embeddedness would rather hinder organizational adaptiveness. This article presents work in progress. To conceptualize research framework we use some pre-existing mental conception of what we are seeking. The aim of the paper is to (1) conceptualize the construct 'endogenous evolutivity' and (2) refer that to the organizational adaptiveness phenomenon.

The method that has been used is deepened literature study. The structure of the paper is four-fold. The first section presents the considerations in the scope of organizational adaptiveness and its strategic rationale. The second part illustrates the endogenous evolutivity concept as routines' embeddedness. Then, the initial research design has been proposed. Finally, the brief conclusion, main limitations and future research directions have been highlighted.

Organizational Adaptiveness: in Search of Strategic Rationale

Professional literature on the subject of strategic management offers a multitude of divagations on the concept of strategic adaptiveness (Hughes & Morgan, 2008; Nordqvist & Melin, 2008), strategic flexibility, fitness, and fluidity. This aspect is analysed in the context of strategy realization potential and describes the need for adjustment between all elements of the organization and its surroundings. This type of adjustment was perceived as a prerequisite for organization's performance. Even today, adjustment criteria are often adopted in the process of evaluating the effectiveness of strategies (Huffman, 2001). Complexity and uncertainty of the surroundings, however, require a new perception of the organizational "fit" idea. At present, it may be more useful to focus on organizational "fitness", i.e., the ability to learn and adapt (Beer et al., 2005). The potential to meet the requirements of changing environment rises in significance. The system of management should be geared towards exploiting and exploring future possibilities and this task can only be facilitated by endless learning as a way to improve operations (Baird & Griffin, 2006). Consequently, the organization may develop the ability to change and react at the operational level (operational flexibility). However, a dynamic organizational system is characterized not only by operational flexibility, but also—and more so—by its strategic flexibility (de Toni & Tonchia, 2005; Matthyssens et al., 2005). Hence, the strategic flexibility constitutes a key success factor and makes strategy

temporal (Eisenhardt, 2002). Flexibility as an ability to do something different from originally intended and as a response to environmental change and uncertainty (Volberda, 1998; Sharma et al., 2010; Gupta & Goyal, 1989) in its various forms has long played an important if not critical role in the organizational change and strategy literature (Dunford et al., 2013; Volberda, 1998).

Specifying, strategic flexibility might be considered as "an organization's capability to identify major changes in the external environment, to quickly commit resources to new courses of action in response to change, and to recognize and act promptly when it is time to halt or reverse such resource commitments'' or as the company's ability to restructure itself internally as well as restructure its relationship with the external environment (Roberts & Stockport, 2009). Quite similarly, Golden and Powel (2000) define flexibility as the organizational capacity to adapt to environmental changes and describe how different conceptions of flexibility vary. Moreover, strategic flexibility is more considered as an organizational process rather than an economic strategy (e.g. Volberda, 1998). What seems to be interesting, Johnson et al (2003) situate strategic flexibility within a resource-based view of the firm: the firm must develop a portfolio of capabilities that creates a bundle of options. The capacity for manoeuvres gained significant importance in management practice and literature (Singh et al., 2013; Roberts & Stockport, 2009) and at the operational level it is created through routines (Heng et al., 2013), at the structural level through adaptiveness and at the strategic level through overall strategies (Volberda, 1998).

Endogenous Evolutivity as Routines' Embeddedness

Endogenous evolutivity constitutes the propensity of a routine to evolve over time (Mickaël & Rowe, 2013). Complexity and uncertainty, interdependence, time pressure are regarded as the antecedents of the stability of routines propensity to evolve (Becker et al., 2005). Additionally, routines are embedded in cultures, technologies, etc., and these may constrain change over time (Howard-Grenville, 2005). The context in which routines are embedded shapes their use and, to a considerable degree, whether and how they alter over time. Howard-Grenville (2005) referred to the embeddedness of routines in technological, cultural, and coordinative structures within an organization, theorizing that routines that were more strongly embedded in these would be more resistant to change over time, even if actors performed them flexibly.

Firms act on the real world through their routines. Firms assess their choice of routines against the alternatives available, and against the performance of their activities relative to those of their competitors. A central argument of evolutionary-based work is that routines or capabilities are the fundamental units of analysis, and that the organization should be conceptualized as the central repository of routines and capabilities (Nelson & Winter, 1982).

Specifying, endogenous evolutivity might be explained by the routines' embeddedness. Strong embeddedness increases variations in routine performances, but not in the abstract general pattern of the routine. Furthermore, there is a natural tendency of routines to become increasingly embedded in resources over time (Guérard & Seidl, 2013).

Research design. Measurement tools and general propositions

Examining the role of endogenous evolutivity in organizational adaptiveness is planned to be conducted by means of the survey amongst team members and leaders in IT enterprises. The choice of the sector is justified with its dynamics what means that in a relatively short period the changes occur and, as a result, the short time of an observation enables to identify the premises of adaptation. Specifying, the following constructs would be examined: endogenous evolutivity and organizational adaptiveness.

Endogenous evolutivity

Endogenous evolutivity is proposed to be measured with the degree of routines' embeddedness. The more embedded routine is the less adaptive it is as well. To measure routines' embeddedness the

Howard-Grenville's (2005) ontology is going to be used (sticky routines: very persistent; little impetus or change from within, accommodative routines, pervasive routines, arbitrary routines, pragmatic routines, and adaptive ones: relatively easily adapted to new uses). The scale has been created on our own – 6 degree Likert scale.

Organizational adaptiveness

Adaptiveness is understood as organizational fit that apart from efficiency and effectiveness constitutes one of the organizational performance measurement indexes (Ruekert et al., 1985). It is going to be measured using the following categories: fluidity, flexibility, and non-financial performance. The fluidity is proposed to be measured using the constructs developed by Doz & Kosonen (2010), i.e. decoupling, modularising, dissociating, switching, and grafting.

Flexibility and its levels are intended to be measured using the categories proposed by Levy & Powell (2005) and Evans (1991): preemptive, exploitive, protective, and corrective flexibility.

Non-financial performance would be measured with the scale proposed by Bolat & Yilmaz (2009) and Tseng & Lee (2014). The Cronbach's alfa is 0.963. The scale consists of twelve items and the exemplary statement to be assessed (7-degree Likert scale) is 'Our company is able to grasp the right timing for launching new products or services.'

The last but not least research remark regards control variables. The most salient control variable for the research proposed seems to be environmental dynamism as it determines the conditions of the research in terms of selected population characteristics (it should concern high-velocity environment – the research is planned to be conducted in the IT sector). The environmental dynamism is proposed to be measured using Schilke's scale (2014). The Cronbach's alfa is 0.81. The measure involves six items and the exemplary statement is 'The modes of production/service change often and in a major way.'

Propositions

Taking into account the considerations aforementioned, the following general propositions have been formulated:

Proposition 1: The higher endogenous evolutivity, the weaker tendency to change the flexibility model from decoupling (customer/segmentation-based value domains) to grafting (acquiring to transform oneself).

Proposition 2: The high endogenous evolutivity implies rather exploitive and protective technology usage than pre-emptive and corrective one.

Proposition 3: The higher endogenous evolutivity, the less company's tendency to vigorously invest on the development of new market and technology and the higher degree of automation operation.

Conclusion

The implication of this framework would be the chance for exploring the associations between organizational routines' embeddedness (endogenous evolutivity) and organizational adaptiveness in terms of fluidity, strategic flexibility, and non-financial performance what contributes to the evolutionary approach complement in terms of studies on organizational routines. With regard to the future research directions, the framework requires empirical examination. The limitation of the study proposed might constitute the fact that not all proposed measures were validated in prior studies.

Adaptive and Organizational Performance
The Role of Routinization and Climate for Innovation

Sylwia Stanczyk, Wroclaw University of Economics, Wroclaw, Poland
sylwia.stanczyk@ue.wroc.pl

Abstract

The purpose of this paper is to argue that the incorporation of climate for innovation perspective and routinization into the study of organizational performance will result in a more complex and broad picture of this phenomenon that will serve to advance the scientific knowledge of adaptive performance and the role routinization plays in the process and to help organizations stimulate responses in face of environmental challenges. Conceptualization on climate for innovation and routinization as constructs that influence adaptive performance and subsequently overall organizational performance is carried out.

Keywords: organizational performance, adaptive performance, routinization, climate for innovation

1. Introduction

The essence of management is coping with change. Recent decades have seen an increased focus on innovation and performance [Tidd & Bessant 2009]. Understanding how organizations overcome significant difficulties and function adaptively has captured the imagination and interest of practitioners and scholars throughout the years. The incorporation of climate for innovation perspective into the study of organizational performance will result in a more complex and broad picture of this phenomenon that will serve to advance the scientific knowledge of adaptive performance and the role routinization plays in the process and to help organizations stimulate responses in face of hard times. Organizational performance is a function of the potential return and managers should consider organizational climate enabling it to execute its routine [Reichard 2002; Schein 2011].

In this paper I conduct a conceptualization on climate for innovation and routinization as constructs that influence adaptive performance and subsequently overall organizational performance. Then, I proceed with rationale for including such constructs in the stream of research focusing on performance to emphasize the main concern of climate for innovation and routinization to build adaptive performance. Finally, I highlight that routinization and climate for innovation can be regarded as evolving insights into organizational performance and adaptation research.

2. Organizational Performance as the central construct

Organizational performance is one of the most important variables in the management research. A research regarding organizational performance has been related to exploring factors that contribute to organizational success. As a result, there is several perspectives organizational performance approaches deal with.

The concept of organizational performance is very common; nevertheless there is not a widely accepted definition of this construct. According to Kaplan & Norton [1993] performance is basically a set of financial and nonfinancial indicators. Hence, organizational performance is in the area of organizational attention as well as the outcome of organizational activities provide strong linkage to the long-term perspective and consequently organizational survival.

On the other hand organizational performance, however, means different things to different organizations. Therefore, there are many parameters an organization may use to measure its

performance. Since the ultimate goal of most business organizations is profitability, most organizations will measure their performance in terms of objective financial data. Nonetheless there are also ample studies that have reported significant correspondences between subjective and objective measures of organizational performance. There is, as would be expected, researcher choice whether he/she employs objective or subjective measures of performance. However, Singh, Darwish and Potočnik [2016] argue that subjective measures can be successfully employed to assess organizational performance. This is because often consistent, reliable and comparable compatible objective data on organizational performance measures is difficult to collect. For instance, Bontis, Crossan and Hulland [2002] developed 10-item scale to collect perceptions of firm performance, arguing that this scale represents a 'reasonable substitute for objective measures of business performance'.

Furthermore, there are numerous research concerning a range of factors influencing organizational performance, such as, human resource management decisions unique influence on organizational performance [Becker & Gerhart 1996], diversity and its impact on organizational performance [Starlene, Simons & Rowland, 2011]; management and leadership and performance [García-Morales, Jiménez-Barrionuevo & Gutiérrez-Gutiérrez 2012], structure impacting performance [Hao, Kasper & Muehlbacher 2012], the impact of organizational culture on organizational performance [Kotter 2012]; along with innovation and performance [Walker, Damanpour & Devece 2011].

Our objective here is to identify and consider climate for innovation and routinization as constructs that influence adaptive performance and subsequently overall organizational performance.

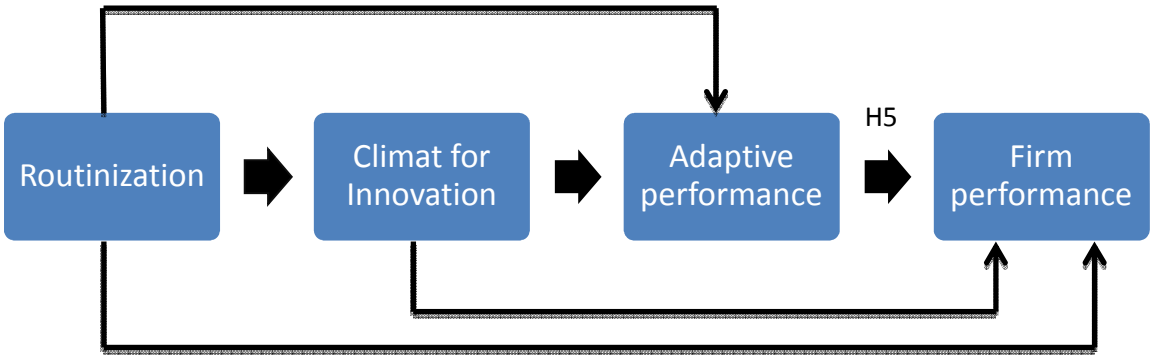

Figure 1: Conceptual Model

The presented research attempts to develop a conceptual model incorporating interrelationships of such constructs, and their effects on the performance, as illustrated in Figure 1. The model comprises two main elements: climate for innovation and routinization. Within the climate for innovation, the model includes five key constructs: team cohesion, supervisory encouragement, resources, autonomy, and openness to innovation [Nybakk, Crespell & Hansen 2011]. Routinization is perceived as frequent social interaction, frequent use of fixed goals, and frequent comparative cost analysis [Becker, Knudsen 2001]. The performance construct is represented by two sub constructs: adaptive performance and organizational performance. As enablers, all of the climate constructs are hypothesized to have a joint direct effect on the adaptive performance and subsequently on

organizational outcomes. Further, the model proposes that routinization as a hinder directly determines the climate for innovation. In addition I hypothesize routinization direct effects on adaptive performance and organizational performance. Finally, a direct relationship between adaptive performance and organizational performance is proposed. Hence I propose following:

H5: Adaptive performance affects firm performance positively.

The next sections further extend the model's constructs, and the rationale behind its development and its presumed relationships with other constructs.

3. Climate for Innovation and performance

Numerous studies have produced evidence which highlights the importance of culture to organizational performance [Wilkins & Ouchi 1983; Kotter & Heskett 1992]. There is a strong view in the literature that organizational culture lead to increased organizational performance. However, an organizational culture impact on organizational performance is characterized by ambiguities. Pearce and Robinson [2004] observe that culture is a strength but can also be a weakness. Nevertheless, organizational culture is a social phenomenon as well as climate conducive to innovation. The later one is especially worth to consider according to the general tendency to innovate. Accordingly, the exact nature of the relationship is mixed.

Organizational culture and performance relation has been examined by many researchers [Ogbonna & Harris 2000; Rousseau 1991; Kotter & Heskett 1992; Marcoulides & Heck 1993], not much research has been done on climate for innovation as a factor influencing organizational performance [Magee 2002].

The concept of organizational climate was first developed by Lewin, Lippitt and White [1939]. Climate represents the behavior, attitudes and feelings of the organization which in turn affect its operational processes in terms of communications, problem solving, decision making and how it learns. A climate for innovation, therefore, is the perception employees hold about innovation in the organization and it consists of workers' feelings, attitudes, and behavioral tendencies measured by their perceptions [Payne & Pugh 1976].

While some theories emphasized on structural forms, adaptability and capability of the organizations as the foundation of the management of organizational performance, other models considered organizational atmosphere, participative management and incentives for innovation as the core requirement for managers to be able to organize and lead organization. Organizational success is indispensably conditioned by the organizational culture and climate. Lawson and Samson [2001] identified four components of organizational climate: a) tolerance of ambiguity by bringing manageable level of uncertainty, putting tight control over project milestones and initiating effective information management; b) empowerment of employees by investing and respecting in people's ability and exceptionality; c) allocation of creative time by allowing flexible deadlines and permeable environment and d) knowledge sharing and communication among within the company and its network by means of cross-technological, cross-hierarchical and cross-functional exchanges.

Innovativeness is described as the propensity to create and/or adopt new products, processes, and or business systems [Knowles et al. 2008]. Innovativeness can be seen as a cultural attribute that captures the openness to new ideas and, hence, an organization's orientation towards innovation [Hurley & Hult 1998]. Climate for innovation is the observable manifestation of a pro-innovation culture and has a positive impact on innovation as does innovation strategy [Crespell & Hansen 2008]. Several scholars have documented a positive relationship between an climate for innovation and performance [e.g. Deshpandé & Farley 2004]. Climate tends to be supportive of an individual's and team's adaptive performance because it creates supportive environment. As such, adaptive performance as well as organizational performance is likely to be complemented by the climate for innovation. Therefore, two following hypotheses are proposed to test:

H3: Climate for innovation affects adaptive performance positively

H4: Climate for innovation affects firm performance positively.

4. Routinization and performance

Within the scope of research, it is assumed that routinization along with climate for innovation affects adaptive performance and firm performance in due course. In order to investigate the relationships among them, the following research hypotheses are developed:

H1: Routinization affects climate for innovation negatively.

H2: Routinization affects adaptive performance negatively.

H6: Routinization affects firm performance negatively.

Research suggests that one way of achieving a strong climate for innovation is through leader behavior [Schein 2011]. The ability to adapt to a changing environment is necessary for the survival of organizations. The role of organizational routines is therefore a fundamental issue. Organizational routines have been regarded as the primary means by which organizations accomplish much of what they do [Nelson & Winter 1982]. In many research, the emphasis is on the constraining characteristic of routines. Sometimes, the advice is that routines have to be 'broken' in order to enable a change. Hence it is important to take into account a dual-role that routines have: routines are seen as not just constraining, but also as enabling [Foss 1996; Hodgson 1997; Foss 1997; Cohen 2007]. According to the different studies, organizational routines result in either inertia or continuous adaptation or in both simultaneously [Mickaël, Frantz 2013]. Organizational routines attract increasing interest among scholars of organization [Parmigiani & Howard-Greenville 2011; Salvato & Rerup 2011]. They promise unique opportunity to explain how organizations change [Nelson & Winter 1982] and why certain organizations surpass others [Abell et al. 2008]. They emerge from the interrelation of individual action. Those who use routines make adjustments to their performances in response to prior outcomes [Feldman 2000]. Becker & Knudsen [2001] selected idea to capture routinization as frequent social interaction (use of task groups), frequent use of fixed goals (for cost control), and frequent comparative cost analysis. As they suggest, this is a useful basis from which a routinization can be measured.

Madhavan et al. [1998] suggested that changes of interaction patterns within routines may be characterized by the "occasions", nature, and direction of structural change. The change of the interaction patterns among members of routines is associated with routinization. The performances of routines are context depended. The context, for instance climate for innovation, may be followed by altered performances what may lead to change of patterns of interaction [Feldman & Pentland 2003] and subsequently to adaptive performance.

7. Concluding remarks

In order to be effective, the organization must adapt to external environmental influences. Without a climate for innovation, it is unlikely that inspired ideas will be transformed into innovation. In the same manner, even though an organization decided to adopt a particular innovation, such innovation is not likely to be fully utilized if the employees perceive no support from the firm. Therefore, to increase organizational performance as well as adaptive performance, it is imperative that the firm ensures the climate for innovation is in place and can be perceived by all members. Naturally, routinization matters. This paper studied climate for innovation and routinization and adaptive and organizational performance on the basis of prior scholars' researches, and build up the contingency model of constructs impacting on organizational performance, proposing organization should pay attention to the impact of intangible organizational aspects on organizational performance

Based on the results, the hypotheses associated with the conceptual model that the two constructs (i.e. routinization, climate for innovation) would influence adaptive performance which, in turn, would influence organizational performance has been formulated.

Abstract

The purpose of this study is to define and describe agile movement and its application to software development and other projects. The agile movement has brought about significant evolution in the process of software development. Its methods have increasingly been adopted globally and as a result, they have become one of the main software development approaches that are used today. It has provided businesses with a much faster and nimbler method for developing software. This is especially important for the ever-growing internet software industry and the emergent mobile technology. To achieve this goal, this study will provide a brief background regarding the development of the movement by focusing on its origin and famous agile manifesto. Characterization of the agile software processes is essential in explaining how the process can be used to shorten the lifecycle of projects. This study will also cover various agile methods that have received recognition in project and software management. In line with this, arguments have been put forth concerning agile projects being more successful than other types of projects. This study will clarify this argument. A set of agile principles that are likely to be applied to all types of projects will also be discussed.

Keywords: agile movement; software development; internet; software industry; characterization; agile principles; agile manifesto; agile methods; agile projects

Introduction

For a long time, the process of project management has been undergoing transformation in terms of information system design. Such evolution of project management in the field of information system does not come as a surprise. Developing systems today has become more than just technically correct or best engineering systems. This is no longer enough for users who currently demand for a system that is practical in nature and can address their specific needs. It is from this perspective that agile movement has been developed. Cervone (2011) defines agile movement as a set of principles used in software development that provides an alternative way of managing projects [1]. It can also be defined as a form of movement for change existing in the sphere of software development methodologies. For the sake of this study agile movement will be used interchangeably with the term agile software development. By providing an alternative way, the agile movement promotes adaptive planning, evolutionary development, early release, and continuous improvement of the software development process [12]. From this perspective, it is used as a way of moving software development away from traditional methods which have been described by agile users as heavy methodologies that lead to projects collecting dust on shelves in documentation. Williams (2010) also states that traditional methods have been found to require a huge effort during their planning phase and more often half of the resources for a project are expended before actual development begins [10].

Literature Review

Dingsøyr, Dyb˚a, and Brede Moe (2011) consider that the rise of the agile movement in the early 2000s can be traced back to the history of software engineering [4]. In 1974, a paper was written introducing an adaptive software development method. By mid 1990s, a collection of lightweight software development techniques evolved in reaction to traditional software development methods which were considered heavily regulated and micro-managed as explained by Dingsøyr, Dyb˚a, and Brede Moe (2011) [4]. Some of these lightweight methods of software development included dynamic system development method (DSDM), scrum, crystal clear, and extreme programming (XP) which were developed in 1994, 1995, 1996, and 1996 respectively according to Corbucci, Goldman, Katayama, Kon, Melo, and Santos (2011) [3]. Thus, the idea of agile techniques has been present since the 1970s and since these lightweight methods were not taken seriously from the beginning, it took them nearly 30 years to become recognized as effective methods of developing software according to Conboy and Fitzgerald (2010) [2].

Agile Overview

The overview will include the agile manifesto which was instrumental in making the software development and project management method become recognized and accepted. The overview will also feature characterization of the agile software development which will provide an insight into how the process shortens the lifecycle of projects.

The Agile Manifesto

The idea of agile software development was accepted and realized in 2001. This happened when a group of independent practitioners with significantly strong links in the software industry decided to come together and establish the agile movement. According to Williams (2010) this group consisted of 17 software experts [10]. The meeting resulted in the crafting of the agile manifesto whose purpose was to popularize the agile movement and produce high quality and valuable software. It was also meant to provide a form of umbrella name that would bring together various lightweight software development approaches that were in existent at the time. The agile manifesto has four main values [1]. The first value is individuals and interactions over processes and tools. This value demonstrates the agile movement's emphasis on the relationship and communality of software developers together with a human role being reflected in contracts instead of institutionalized processes and tools. The second value of the manifesto is working out software for comprehensive documentation. This value aims to show that the main goal of a software team is to continuously turn out tested software within a short time frame while keeping code simple and straightforward so as to reduce documentation. The third value is customer collaboration over contract negotiation. This means that the relationship formed between software developers and customers was more meaningful compared to ordinary contracts. The final value of the manifesto is responding to change by following a plan. This value means that a development group which was to be comprised of software developers and customer representatives ought to be well informed, competent, and authorized to place any form of consideration on possible adjustment needs that may emerge during the process of development.

Following the formation of the manifesto, some of its authors came together and formed a nonprofit organization known as the Agile Alliance. Its purpose was to promote software development according to the values and principles of the formulated manifesto. Santos and Goldman (2011) make the assertion; the one thing that is new about the agile methods of software development is the recognition of people as the main drivers of the success of a project together with a deep focus on effectiveness and maneuverability.

Characterization

Santos and Goldman (2011) provides the following characteristics of the agile software development process [9]. Most of the characteristics involve a fast delivery perspective that focuses on shortening the lifecycle of a project. One of such characteristics is incremental process approach. This approach allows functioning application to be built in small steps. This makes the application building be carried out in a manner that makes it possible to identify any kinks in the process thus ensuring high quality results. Another significant characteristic of the agile software development process is the fact that it is people oriented. In this sense, the process values people over process, procedures, and technology. This makes the end result be something that actually meets the needs of people who are the reason for the software development. Software that is developed via the agile process has parsimony. Parsimony in the development process is essential for the elimination of all activities that are deemed to be unnecessary. This makes the process of software development more effective and faster. A final characteristic of agile software development process is the fact that it is time bound with iteration cycles that run from one to six weeks. This is noteworthy because it leads to weekly production of the first delivery that makes it possible to achieve an early win and rapid feedback.

Agile Methods

There a number of software development methods following the values and principles of the agile movement. They are referred to as agile software development methods. Four agile software development methods will be discussed. The methods will be reviewed in a systematic way. This will entail discussing the method process, role and responsibilities, scope of use and the current research regarding them. Two main agile methods that will be highlighted are Extreme Programming and Scrum.

A. Extreme Programming (XP)

XP is an agile development method that affirms simplicity, feedback, and community in software development. The method has brought about evolution by eliminating many of the problems that were caused by traditional development cycles. The method was named extreme as a result of taking common development principles and practices and pushing them to extreme levels.

Process: The XP development process is encompassed of three iterative phases [4]. The three phases are planning, development, and acceptance. Planning is carried out at the beginning of a project. It entails dividing the project into iterations of 1 to3 weeks. Furthermore, during this phase story cards representing features of the project are created and the release date of the project is established. During the second phase the actual development begins with the high level design sketch being placed on a white board. At this phase, two programming teams are formed and programming is carried out in pairs whereby both team members are given the same responsibilities for a given code. In the last face of acceptance, the whole code developed by the team members is tested by an automated acceptance test that is chosen by a customer. A review meeting is then held with the aim of giving a feedback.

Role and Responsibilities: According to Corbucci, Goldman, Katayama, Kon, Melo, and Santos (2011), there exist different roles in XP intended for different tasks and purposes [3]. Some of the most vital roles include the following. The first role is that of a programmer. In this sense, programmers are charged with the task of writing up tests and keeping the program code simple and well-defined. This process equally entails communication and coordination with fellow programmers. The second role is that of the customer. The customer usually writes functional tests and is the one who decides that a requirement has been met. They also establish the implementation priority for the requirements. Tester plays another role. The tester aids the customer in writing the functional test. They are also in charge of running the developed functional tests on a regular basis and disseminate information on the results of the tests to concerned parties.

Scope of Use: The scope of the use of XP is limited as it is not suitable for being used everywhere as a result of its restrictions. For instance, the use of XP is oriented on small and medium sized teams. Cervone (2011) affirms that the size of these teams has to be within the range of 3 to 20 members [1]. In regard to the physical environment where the project is supposed to take place the team members must be able to communicate and coordinate with each other effectively.

Current Research: According to Santos and Goldman (2011), research on XP is still growing [9]. There are a significant number of studies on various aspects of XP. However, due to the development method being perceived more as a practical one, most of these studies are focused on individuals' experiences regarding the use of XP.

B. Scrum

This is a lightweight agile project management framework. It is extensively applied for managing and controlling iterative and also incremental projects. It is usually perceived as an empirical approach that applies ideas and theories of industrial process control to the development of systems. This results in the development of an approach that seeks to reintroduce flexibility, adaptability, and productivity in project development.

Process: The process of the scrum method consists of four main phases; planning, staging, development, and release. The purpose of the planning phase is to establish the goal vision and expectations that the project will be undertaken and the necessary funding for it will be allocated. All this is usually accomplished during pre-game planning. It is also vital to note that the project is usually subdivided into iterations known as sprints. During staging which is the second phase of scrum, requirements for the project are identified. Priorities are then established for iteration. Therefore, this stage starts with sprint planning that helps to lay down the plan for iteration. During the process of prioritizing external stakeholders are usually engaged. Following the creation of the plan, there can be no additional sprints. During the third phase of development, a systems implementation is carried out during a period of 30 days of iterations [2]. It is then prepared for release following this implementation. In addition, during this phase, the work in sprints is usually divided into daily blocks that bring daily builds. Conboy and Fitzgerald (2010) further affirms that meetings are held on a daily basis for approximately 15 minutes in which the status of the sprints is updated [2]. In addition, it is during these meetings that team members select what tasks they are going to be working on next. In the final phase of release, the system is deployed. This involves presenting a system to external stakeholders with the aim of receiving feedback. After reviewing the feedback received, future directions are then set.

Role and Responsibilities: Some of the major roles and responsibilities of Scrum assigned with different tasks during its practices include Scrum master, product owner, and Scrum team [3]. The Scrum Master is a management role that is responsible for making sure that a project is completed according to practices, values, and rules of Scrum. Product owner is the one who is responsible for a project. The Scrum team refers to the project team which has the authority to make decisions regarding the actions necessary for achieving goals of sprints made.

Scope of Use: The scope of use of the Scrum method is small teams encompassing of less than 10 members according to Williams (2010) [10]. In the event that there are more people, more teams will have to be created.

Current Research: According to Imran (2016), the latest research aims to integrate XP and Scrum [5]. This is because Scrum is able to provide a project management framework that can be supported by XP practices. More research is being conducted to provide more information on this aspect.

Agile Principles

There are some agile principles that can be applied to all types of projects and not just necessarily software development alone. Some people question whether agile methodologies can be implemented

for any kind of project. This is because the iterative, cooperative, and user focused approach seems to be suitable only for certain types of projects such as XP related ones. The truth however is that agile methodologies and in particular principles are suitable for all types of projects. Some of the agile principles that are suitable for all types of projects include the following. One of such principles is working in smaller chunks. According to Conboy and Fitzgerald (2010), this means that requirements and tasks can be broken down into much smaller and easily manageable chunks [2]. This will help to complete a project in a shorter time period that can range from days to several weeks. This will be essential for ensuring that tasks will not end up taking more resources than those originally allocated for them. Another significant agile principle that can be applied to all projects is the principle of seeking quick feedback and continuous improvement. This applies to all projects because the truth is that this involves criticism which is a bottleneck to improvement. Santos and Goldman (2011) explain that this is because human nature detests being criticized [9]. However, criticism is necessary for not only software development but for all other types of projects because it allows for mistake to be identified in good time and thus ensures that only the best results are achieved.

Embracing change and working accordingly is another agile principle that can be applied to all types of projects. It is imperative to realize that no matter how hard one works on a project and how well they plan for it, the truth is that unexpected things happen all the time which forces developers to adjust their plans. This does not happen in software development alone, but in all other kinds of processes and projects according to Moe, Dingsoyr, and Dyb˚a (2010) [7]. Thus, in terms of projects development, this can be handled by planning less for long term processes since it is not possible to foresee the future. It is advisable to seek feedback on a project sooner rather than later so as to avoid making changes to a project when there is little time left for it to be completed.

Success of Agile Projects

It has been claimed that agile projects are more successful than other types of projects. This to a great extent is true. This is because there is evidence in support of this claim. The success of agile projects is based on projects being on time, on budget, and containing all the planned features. Evidence supporting this claim is provided in a study that was conducted by Mah (2012) in which he concludes that results from participants in the Columbus area demonstrate a business system which is comprised of 50000 lines of code that can be completed by 31% faster compared to industry average [6]. This can be found in the QSM industry database of projects that have been completed. These results were obtained following the analysis of agile methodologies of a programming community in Columbus. The purpose of the study was to provide answers concerning the development projects that were scheduled and budgets.

More significant evidence illustrating that agile projects are more successful than other types of projects is provided in a study by Rico (2008) who affirms that an early study of agile project management illustrates 10 to 20 percent improvement in revenues, quality, and cycle time [8]. Rico (2008) further conducted another study in which he showed 50 to 60 reductions in cost and a staggering ten times flexibility in development [8]. Rico states in his study that the agile project management benefits are a result of various factors however the main factors are productivity and quality [8].

Personal Experience and Opinion

The first time that I was introduced to the agile movement and its methods, I found it to be a bit difficult to comprehend. This is because of its nature of being different from the traditional methods that I was used to. Agile methods significantly reduce the amount of documentation, and even claim that the code itself should act as a document [13]. Agile methodologies are well-known for emphasizing in communication and customer involvement [11]. Agile software development methods were developed to provide more customer satisfaction, to shorten the development life cycle, to reduce bug rates, and to accommodate changing business requirement during the development process [12]. In general, the use of agile development is that at the moment it is the best way of project and software development [13]. I found some of my colleagues' have opinion that agile

software development is harder and more confusing, the process has no methodology and is chaotic. This claim is far from being true. It is true that the process offers a certain degree of freedom to software development and project management, but it does follow any form of order. The only difference is that the level of rules and regulations including documentation has been decreased. The truth is that using agile methods for project development is actually advantageous [13].

Conclusion

In conclusion, since its inception in the 1970s and its recognition in the early 2000s, the agile movement has proved to be a leading software development and project management method that has been praised in many fields. The agile manifesto which is credited with bringing the agile methods into the lime light in 2001 also brought about a way of organizing various lightweight software development methods. Therefore, it paved way for agile methods to be developed in a manner that brought about clarity as to what they were all about. The characterization of the agile software development process presents them as fast delivery methods that aim to focus on shortening the lifecycle of projects. Currently, there are a number of agile methodologies that have been developed. XP and Scrum are some of the commonly known examples. Researchers continue to carry out additional research on these methods in a bid to fill the gaps which have been left by previous research. Agile projects have been proved to be more successful than other types of projects. Studies conducted have shown that projects developed via agile methodologies are usually on time, budget, and contain all the featured plans. The process has proven to be so effective that some agile principles are being applied to all kinds of projects. Therefore, the use of agile methods is significant in changing software development and project management process whereas in IT projects, selecting developing methodology is a complex decision. IT project managers need to consider project size, risk, time, complexity, available, user requirements, resources, business priority for projects and other factors.

Abstract

This exploratory study seeks to understand the characteristics of high achievers for the Bachelor of Accountancy Program. Data on 67 high performing students' are obtained from the university's records database. The instrument for this study was a survey questionnaire, administered to third-year undergraduate accounting students who scored cumulative grade point average (CGPA) of 3.5 and above out of 4.0. A set of questions were prepared to measure students' motivation, learning time and effort. The findings indicate that majority of high achievers are female (86.6%), and 97 percentage of them pursuing bachelor accounting degree to satisfy their personal goal or to continue a career that they love. Sample students are with a very high pre-admission grade. Regarding specific characteristics of high achievers, the results show that they are highly motivated students, and put a great effort into their studies that help them to succeed in their academics. The results also provide evidence that on average, students who entered with diploma scored higher grade point average (GPA) in their third-year examination in comparison to students who entered bachelor degree with matriculations. However, no difference in the overall performance (CGPA) between these two groups indicating, students who enter the program from matriculation were not able to maintain their performance when the subjects become tougher at the higher level.

Keywords: Academic performance, accounting students, accounting knowledge, motivation.

Introduction

Malaysia needs about 60,000 accountants to become a developed nation by 2020. However, despite hundreds of accounting graduates produced every year, the country is still facing the shortage of accredited accountant especially bumiputra accountant. To date, there are approximately 32,000 professional accountants in Malaysia. This shortage is perhaps due to many of bumiputra accounting students graduated with average performance and therefore not interested in pursuing professional accounting qualification or accounting career after graduation.

This study forms part of an ongoing investigation into factors affecting accounting undergraduate program achievement at a Malaysia public university. More specifically, the study examines students' pre-admission qualification performance, their endogenous factors of motivation, effort, and learning styles. The preliminary results of attributes of high achievers will enhance the university and educators understanding of issues which affect students' achievement in higher education.

Literature Review

Research in accounting education has been an important area of research that provides a significant contribution towards education development particularly in higher education institutions (HEI). Understanding factors that may influence students' performance is important to help the institutions achieve their objective to produce students with excellent academic performance. Considerable prior literature focuses on students profiling to examine factors that may influence students' performance

in HEI (Muller & Prinsloo, 2007; Trejos & Barboza, 2008; Diseth, Pallesen, Brunborg & Larsen, 2010). Muller and Prinsloo (2007) for example, examined the profile of successful accounting student using the Chi Square Automatic Interaction Detector (CHAID) technique.

Findings from the research show students who obtained high academic achievement are those having high motivation in their studies and also able to manage their time effectively. Trejos and Barboza (2008) in another study, examined the relative contribution of students' characteristic on performance. Finding is consistent with Muller and Prinsloo (2007) which found that effort is relevant and statistically significant factor in determining student's performance. Using profile analysis, Diseth, Pallesen, Brunborg & Larsen (2010) also found effort particularly the amount of time spent on studying found to be significant predictors of performance and academic achievement.

Prior research has produced contradictory findings in the relation between prior accounting knowledge and academic performance (Waples & Daraysey, 2005; Baldwin and Howe (1982); Mooi Tho, 1994). Having accounting foundation does not necessarily help the students to perform better in future (Baldwin and Howe (1982). He found no difference in the performance between the two groups. Those with basic accounting knowledge perform better in earlier examinations, but their performance has dropped later. Additionally, there is also no difference in the dropout rate between the two (2) groups. However, a study in a Malaysian Public University found the basic knowledge in accounting, mathematics and economics obtained at high school level are three (3) academic factors that influence the students' performance in the first tertiary accounting course (Mooi Tho, 1994).

The same evidence documented by Waples & Daraysey, (2005) who found that students with basic accounting knowledge and high overall academic ability have the better opportunity to perform well in the intermediate accounting subjects. A Proper foundation of basic financial accounting knowledge (measured based on cumulative GPA before enrollment), passing grade in introductory financial accounting and introductory managerial accounting and score on diagnostic assessment are important indicators of students to perform well in their accounting studies (Waples & Daraysey, 2005). To understand the issues better, Mooi Tho (1994) also suggest extending the accounting education research in the Malaysian context, to examine the influence of other factors such as students effort, personality, learning styles and students' economic and social background on the academic performance.

Data collection and measurement of variables

The sample comprises of third-year dean's list students at the Faculty of Accountancy, Universiti Teknologi MARA Malaysia. Dean's List students are students who scored cumulative CGPA of 3.5 and above out of 4.0 for the semester of study. Students are admitted based on their performance in the Diploma in Accounting (DIA), or the Sijil Matriculation from Ministry of Higher Education. The entrance of students into the Bachelor of Accountancy (BACC) program is determined by the overall performance measured in terms of student's CGPA in the DIA or Matriculation.

Students' achievements at the BACC program are measured by their overall GPA (CGPA), and their grade point average (GPA) scored in the most recent examinations in Jan 2016. Endogenous factors of pre-admission academic performance, gender, study effort, motivation, and extended learning time are examined. Study effort, motivation and learning time are measured by a set of items included in the questionnaire. There are four items used to measure study effort and five items each for both motivation and learning time. The maximum score for each item is 20, 25 and 25 respectively.

Findings

Table 1 presents the sample students by pre-admission qualification. The result shows that out of 67 dean's list students included in the sample, only twenty-four students or 35.8 percent are students who entered with matriculation qualification. Another forty-three or 64.2 percent are students who entered with DIA as the pre-admission qualification. The statistics also show that High achievers are

students with high pre-admission academic performance with average CGPA of above 3.50 out of maximum score of 4.00.

Table 1: Sample students by pre-admission qualification

	Sample students N (%)	Pre-admission qualification (mean CGPA Diploma or Matriculation)
Diploma Entry students	43 (64.18%)	3.79
Matriculation Entry students	24 (35.82%)	3.94

Table 2: Sample students by gender

Female N (%)	Male N (%)	Total N (%)
58 (86.6%)	9 (13.4%)	67 (100%)

Table 2 presents the sample of study by gender. The statistic shows that out of 67 dean's list student, only nine or 13.4 percent are male students while another 58 (86.6%) are female. This statistic indicates the majority of high achievers are female. This observation is consistent with the result of Tho (1994) who reports superior female performance in accounting in a Malaysia setting.

Table 3: Descriptive statistics

Variable	Max score	Mean	Std. Dev.
GPA	4.00	3.57	0.250
CGPA	4.00	3.58	0.116
Effort	20	17.55	1.869
Motivation	25	19.92	2.439
Learning time	25	20.39	2.668

Tables 3 presents the descriptive statistics for the recent semester academic performance (GPA), overall performance (CGPA), and mean score for three students endogenous factors. It can be noted that the mean score of recent examination result (GPA) is slightly lower than the average cumulative grade point (CGPA). This indicates, on average, students scored lower grade in current semester compared to the previous semester. These perhaps explained by the difficulty in the courses at the higher level of the program.

In terms of students endogenous factors, statistics above show that dean's list students are students who are highly motivated and put great effort into their studies. The statistics also shows that high achievers spend more time on learning the subject outside the classroom. Empirical studies documented evidence that formal learning time in the classroom positively associated with performance. However, due to economic benefit of shorter class contact, it is suggested that extended learning time may help to raise participants' academic performance (Ismail and Ali, 2015).

The high motivation of the students is reflected in other findings of the survey. Statistics in Table 4 shows that 97 percent of the students pursuing a bachelor degree in accounting to satisfy their personal goal and majority of them (64.2%) enrolled because of the reputation of the program and not for other reasons (refer Table 5).

Table 4: Motivation for pursuing bachelor accounting degree

	Number of students	%
Satisfy a personal goal to pursue a career that I love	65	97
Follow the advice of a parent or guardian	2	3

Table 5: Reason for choosing the faculty and University

	Number of students	%
Reputation of the program	43	64.2%
Convenience/near home town	5	7.4%
Financial incentive (relative lowest cost of tuition, scholarship, etc.)	19	28.4%

Table 6 presents the results of students' performance in their third-year final examination which was conducted in January 2016. Comparing their grade point average by entry qualification, the results show that GPA of DIA admission student is significantly higher in comparison to the other group of students. The GPA of DIA entry students is 3.62 compared to 3.47 for matriculation students' and the mean difference is significant at the 5 percent level.

The result also indicates that students who entered the program using matriculation qualification on average did not get dean's list status for their third-year examination. The difference in CGPA is however not significant which probably due to higher GPA scored by matriculation entry students at the lower level of bachelor degree program. Indirectly, this indicates they are not able to maintain their performance when the subjects become tougher at the higher level of the program.

Table 6: Students' performance in the third year examination

Student's entry qualification	n	Mean GPA	t-stats (sig.)	Mean CGPA	t-stats (sig.)
DIA	43	3.62	2.41	3.59	0.844
Matriculation	24	3.47	(0.019)	3.56	(0.402)

Conclusions and directions for future research

This study explored the attributes of the high performer in their bachelor of accounting program. It found that high academic achievement students are students with high pre-admission academic achievement, are highly motivated, put considerable effort into their study and they voluntarily extending their learning time. The results also found that students who entered with the diploma as pre-admission qualification performed better than matriculation students in their third-year examination. However, no difference in the overall performance between these two groups indicating, students who enter the program from matriculation were not able to maintain their performance when the subjects become tougher at the higher level. Future study may want to extend the sample students to test whether the attributes of high achievers documented in this study are factors determining the achievement of accounting students.

Abstract

In the context of Europe 2020 Strategy, smart growth is strongly linked with research/innovation through public and private investments in order to create a better environment for research, development and innovation processes. One of the key aspect (at the EU level but mainly at the country level) is the reinforcement of universities collaboration with actors of the business environment, particular with industry. This will support innovation and will positive impact all the European targets of the Vision 2020. In this context, the article research aims to present an evaluation model for the university-industry collaboration in open innovation. The approach's core consists of a related ontology of the university-industry collaboration development based on the reference review and the creative common work of a research group of experts. The ontology dimensions and their characterization items were chosen based on the theory of the university new role in the society. Furthermore, the ontology structure and elements has contributed to the development of a survey based on a questionnaire for the university-industry collaboration diagnosis (considering the university local, regional market) and it has been proofed as an effective support of the decision-making process when establishing a contract, project, or partnership with industrial or business organizations. The proposed evaluation model has been tested and validated in the case of three Romanian universities. Based on the applicative research results a business model for the university-industry collaboration in open innovation has been proposed and it is debated in this article.

Keywords: university-industry collaboration, innovation, business model.

1. Introduction

1.1. European Requirements in the Vision 2020

In the context of Europe 2020 Strategy 92010), smart growth is strongly linked with research/innovation in order to combine public and private investment and to reach 3% of EU's GDP as well as better conditions for research, development and innovation processes. In this requirement context, one of the key aspect (at the EU level but mainly at the country level) is reinforced of universities collaboration with actors of the business environment. Beside these aspects, there is a strong need for industrial modernization in Europe, and these could be based on *innovative business models*, that include cooperation with different stakeholders, as universities, public or private research institutions.

There are two key constraints to enhance collaboration between academia and business, in accordance with the European Commission report done by Idea Consulting in 2012: "the low absorptive capacity of enterprises for research and a gap in the availability of applied research capability that enterprises can readily access. Policy makers can assist in closing this gap by stimulating industry collaboration in small and large research programs. In addition, support to companies to (temporarily) employ an academic or (PhD) student can stimulate the transfer of knowledge between academia and industry".

In Romania, policy makers have tried to close these gaps by requiring large partnership research projects, most of them involving industry collaboration. In the last years, it has been established a common practice that project proposals (of different types) are more competitive for funding if they

include some commitment to collaboration with industry or they are developed in a partnership with different actors or stakeholders from business environment.

The article will present an example of good practice of universities-industry collaboration and the description of a proposed business model that have been developed. The research aims to demonstrate the feasibility of the research approach that consists of the following stages: (1) the definition of the university-industry collaboration ontology in order to activate open innovation between partners; (2) demonstration of the ontology usefulness in the case of evaluating the state of university involvement in such collaborations; (3) description of the proposed business model for the university-industry collaboration. The theoretical researches are associated with research results, debates and good practice, from three Romanian universities.

1.2. A Changing Paradigm of Universities New Roles in the Knowledge and Innovation Economy

In present times, universities (as public or private bodies) have extent their traditional roles (or primary functions) of education and research, to an integrative one, more related to society. Different approaches as the Entrepreneurship University and Knowledge-Based University were developed in order to explain the new meaning and content to the traditional role of these types of organizations. In some previous research studies done by Draghici et al. (2015a, 2015b, 2015c) the development tendencies of higher institutions together with the analysis and evaluation of their innovation potential (including their capacity for the transfer of innovation and knowledge) Has been shown. These studies have underline the research and innovation specific in the case of three Romanian universities together with some remarks related to their development at the European Level.

The previous work developed by Draghici et al. (2015a, 2015b, 2015c) try to extend the concepts (and define a framework of collaboration) presented in the research done by Nonaka et al. (2000), where there have been described the way university could be considered as a BA space included in the BA of different actors in the market where they operate. Networking and involvement in different communities are important aspects of university BA space creation. This approach could be seen as a generalized one and that do not exclude the developments related to the dynamics of universities innovation models as Model 2, the Triple Helix of university-industry-government relations, presented by Etzkowitz and Leydesdorff (2000).

Furthermore, as presented in the book edited by Curaj et al. (2012), today European universities' third mission is focused on engagement with wider society. This third mission is strong related to the technology transfer (including knowledge and innovation) to industry or economic partners, participation in policy making or in public engagement and societal debate. There have been recognized that an important element of the universities third mission is their role in addressing societal challenges. The pillars of the Europe 2020 strategy reflect this fact (considered in the European agenda for the next years), too. In addition, Curaj et al. (2012) has sustained that this agenda puts forward three mutually reinforcing priorities: Smart Growth, Sustainable Growth and Inclusive Growth, which are further divided into seven flagship initiatives to catalyse progress under each priority theme.

Above all these considerations there can be seen that the ideas and tendencies presented by Curaj et al. (2012) in their book are strongly related to the dynamics of the university BA space and the way changes are managed in order to support the new business models that include strategies on how education and research are done, but also, how their results are valorised for the benefit of the entire society.

In addition, the academic enterprise concept was introduced, defined and characterized by Kwiek (2013), at the European level, in an integrative manner by taking into consideration the broad features of concept complexity as they are described in Fig. 1. Kwiek (2013) has recognized that, the pressure of last year's (perpetual) reform in Europe affects the European academic enterprises: "in all ongoing reform initiatives throughout Europe, there is a hidden dynamics of changes in relationships between the state, or the major sponsor of teaching and research, and academics, or the major beneficiary of state sponsorship of the academic enterprise".

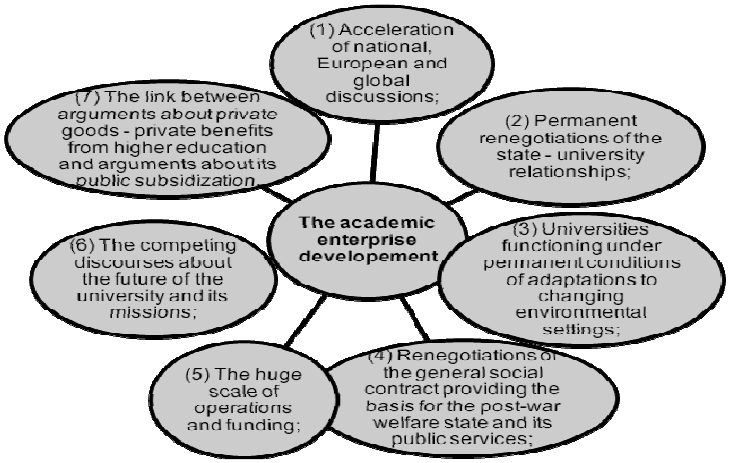

Fig. 1: Features of the academic enterprise complexity

Started from these considerations, the article presents the research approach for defining an evaluation model, based on a related ontology, for the university-industry collaboration in open innovation. Furthermore, the proposed methodology has been tested and validated in the case of three Romanian universities and based on the experimental results a global overview or diagnosis was done. The following chapters will described the research approach.

2. The Ontology of the University-Industry Collaboration

The study of Chesbrough (2003) was underlining that in the last period, universities have moved from a so call, "closed innovation system" to an "open innovation system". Other researchers' studies as Geuna and Muscio (2009), Larédo (2003), Draghici et al. (2015a) were concerned of the university implications in open innovation processes.

While the term "open" may include a number of factors as legal, economic etc., the process of supporting and encouraging networking (for innovation increasing) refers to public-private partnerships as university-industry cooperation or collaboration. Researchers and practitioners from the academia have considered this new innovation context as a key element for the European universities (particular to their research units). Massen and Stensaker (2011) have underlined that universities "play a leading global role in terms of top-level scientific output, but lag behind in the ability of converting this strength into wealth-generating innovations".

Taking into consideration the new changes and challenges for the case of university-industry collaboration, there have been established the research approach with the aim of identifying and characterising Romanian universities level of development in open innovation (by considering their third mission and their potential of collaboration with business actors). The phases of the adopted methodology are shown in Fig. 2. The following chapters of the article will present the research results and findings by followed the suggested phases.

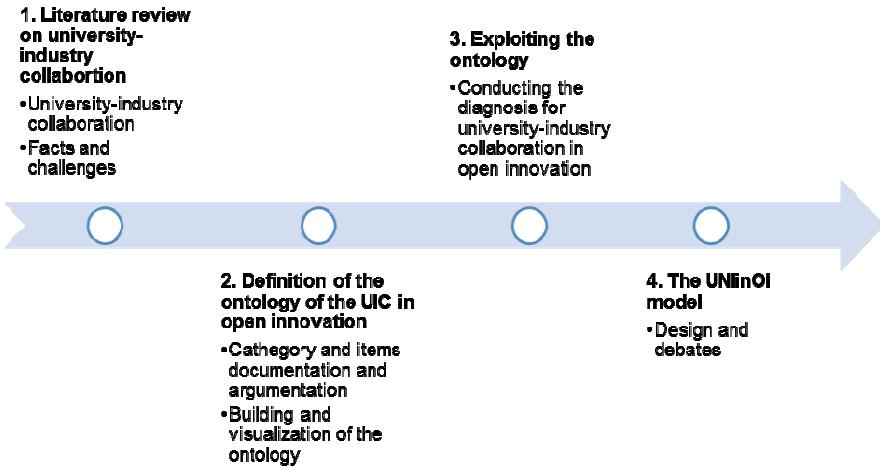

Fig. 2: The research methodology schema

2.1. The University-Industry Collaboration Ontology Definition

In order to define a coherent model of the university-industry collaboration, after the first phase there have been created the conditions for the creative work related to the ontology definition (second research phase). The established framework consists of five dimensions described by 30 relevant items, which could be considered then for the evaluation model. The main issues of interest are (inspired mainly from the study of Ankrah (2007) and analysed by Draghici et al. (2015a)): 1) Identification of motivation factors (8 items); 2) Barriers (8 issues); 3) Channels for the knowledge transfer (7 issues); 4) Benefits (3 issues); 5) Disadvantages of the university-industry collaboration in the open innovation context (4 issues). Fig. 3 described the main branches of the designed ontology.

The preliminary literature review have conducted to the establishment of the issues or factors of interest on each category (main branches) considered in the ontology:

1) Issues related to the identification of motivation factors for established based on researches described by Ankrah (2007), Padilla-Melendez and Garrido-Moreno (2012), and Van de Vrande et al. (2009);
2) The characterization issues for the barriers or obstacles that could appears in the university-industry collaboration were based on the studies of Bruneel et al. (2010), Howells et al. (2012), and Van der Meer (2007);
3) The issues that are of great interest for the channels for the knowledge transfer between university and industry partners were considered similar as in the case of previous researches done by Bruneel et al. (2010), and Alexander and Martin (2013);
4) Benefits of the university-industry collaboration were characterized through three issues similar to the research described by Ankrah (2007);
5) Disadvantages of the university-industry collaboration in the open innovation context were considered similar to those of the research done by Ankrah (2007).

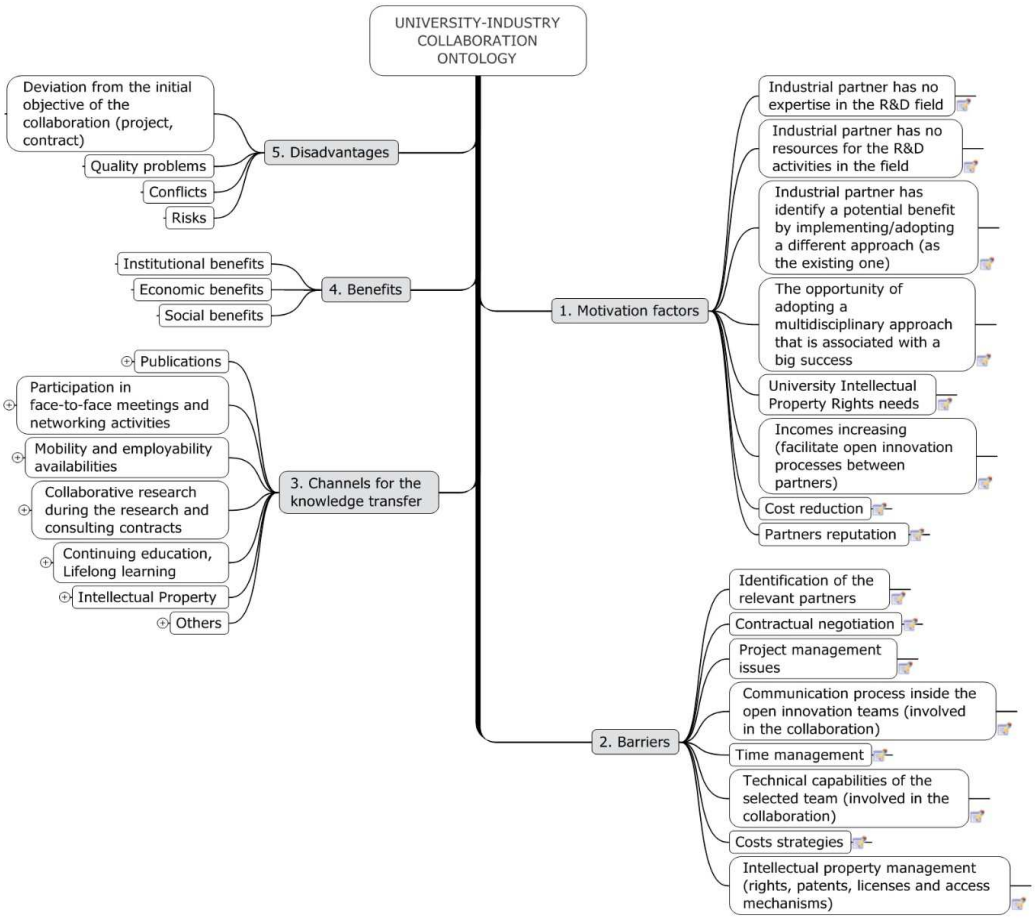

Fig. 3: The university-industry collaboration ontology general overview (knowledge map)

2.2. Ontology Visualization

The ontology design is a result of a creative work developed in a collaborative manner with specialists from three universities in Romania. Using their experience and expertise in university-industry collaborations, the ontology was used as a basis for the evaluation approach regarding the state of Romanian universities involvement in collaborative projects or contract with actors from the business environment (particularly with industrial actors). In order to achieve this task, several face-to-face and virtual sessions of the researchers were developed in a collaborative manner, from October 2014 till July 2015. The university-industry collaboration ontology versions' visualization have been done using the facilities of the MindManager software tool. This has been a useful tool for the graphical modelling of the designed ontology, too.

3. Ontology Exploitation: the Evaluation Model for University-Industry Collaboration in Open Innovation

3.1. Evaluation Model Development – Methodological Aspects

In the third phase of the research, the university-industry collaboration ontology categories and items has been used for designing a questionnaire. This was considered the tool to support the survey for the characterization of the main dimensions of the university-industry collaboration in open innovation. The designed questionnaire allow the collection of responses related to each category and items (same as in the previous designed ontology but with an adequate formulation). Respondents' opinions (answers) were evaluated based on the Likert scale with 5 points (1, totally disagree /

unimportant, …, 5, totally agree / very important). The categories considered for the analysis together with their items for characterization were codifying as shown in Table 1. In addition, there was established a mathematical model for the related scores calculated for each category (dimension, in this case: D1, D2, D3, D4 and D5) and also, for the total score of the evaluation approach (T). The mathematical formulas used for the scores calculation are shown in Table 1. In the case of the dimension D3 "channels for knowledge transfer", there was included an open question that was not considered for the mathematical approach. Finally, the developed model for the evaluation of the university-industry collaboration in open innovation consists of 5 dimensions and 29 related items.

The questionnaire was distributed on-line in the case of three research communities that belong to three public universities (managers from different levels of the research domain and research staff were subjects of the survey). The collected responses were processed (using Excel software facilities) by each university responsible person and the global research results were determined as a university-industry collaboration foot print (radar graphic) and by calculated a total score.

Table 1: The university-industry collaboration foot print determination based on the designed ontology presented in Fig. 3 (the mathematical model adopted)

Code	Dimension	Score / Item / Dimensions' score
D1	Motivation factors	$X_1 \dots X_8$ – absolute value of the score by each item of characterization $X_i = (1\,x_1 + 2\,x_2 + 3\,x_3 + 4\,x_4 + 5\,x_5) / 5,\ i = 1, \dots, 8$ $x_1 \dots x_5$ – number of responses related to the Likert scale points $D1 = (\sum X_i) / 8,\ i = 1, \dots, 8$
D2	Barriers	$X_1 \dots X_8$ – absolute value of the score by each item of characterization $X_i = (1\,x_1 + 2\,x_2 + 3\,x_3 + 4\,x_4 + 5\,x_5) / 5,\ i = 1, \dots, 8$ $x_1 \dots x_5$ – number of responses related to the Likert scale points $D2 = (\sum X_i) / 8,\ i = 1, \dots, 8$
D3	Channels for the knowledge transfer	$X_1 \dots X_6$ (X_7 was transformed into an open question) – absolute value of the score by each item of characterization $X_i = (1\,x_1 + 2\,x_2 + 3\,x_3 + 4\,x_4 + 5\,x_5) / 5,\ i = 1, \dots, 6$ $x_1 \dots x_5$ – number of responses related to the Likert scale points $D3 = (\sum X_i) / 6,\ i = 1, \dots, 6$
D4	Benefits	$X_1 \dots X_3$ – absolute value of the score by each item of characterization $X_i = (1\,x_1 + 2\,x_2 + 3\,x_3 + 4\,x_4 + 5\,x_5) / 5,\ i = 1, \dots, 3$ $x_1 \dots x_5$ – number of responses related to the Likert scale points $D4 = (\sum X_i) / 3,\ i = 1, \dots, 3$
D5	Disadvantages	$X_1 \dots X_4$ – absolute value of the score by each item of characterization $X_i = (1\,x_1 + 2\,x_2 + 3\,x_3 + 4\,x_4 + 5\,x_5) / 5,\ i = 1, \dots, 4$ $x_1 \dots x_5$ – number of responses related to the Likert scale points $D5 = (\sum X_i) / 4,\ i = 1, \dots, 4$
T	Total score	$T = (D1 + D2 + D3 + D4 + D5) / 5$

3.2. Evaluation Methodology into Action: Experimental Research Results

Table 2 presents the research results gained after the responds were processed, for each university responsible. In Fig. 4 are presented the university-industry collaboration foot print graphs for each universities involved in the research together with the global graph.

Table 2: Research results

Calculations results for the dimension, D_i, *i = 1, …, 4*		
Politehnica University of Timisoara - UPT (212 subjects)	University of Oradea - UO (154 in the subjects)	Technical University of Cluj-Napoca – UTCluj (232 subjects)
D1 = 3.784788	D1 = 3.857955	D1 = 3.745151
D2 = 3.898585	D2 = 4.112825	D2 = 3.967134
D3 = 3.242138	D3 = 3.494589	D3 = 3.41822
D4 = 3.281447	D4 = 3.500000	D4 = 3.346264
D5 = 3.542453	D5 = 3.435065	D5 = 3.479526
T_{UPT} = 3.55	T_{UO} = 3.68	T_{UTCluj} = 3.59
Global score for all three universities: T_{global} = 3.61		

The research results show similar opinions and attitude of the subjects related to the university-industry collaboration in open innovation. The Total/university (3.55; 3.68 and 3.59) and the global scores of 3.61 demonstrate the existing collaboration with difficulties of strategic and tactics related to complete attending of the universities objectives and in the field of knowledge, innovation transfer. Furthermore, Romanian universities do not have a coherent business model (definition, implementation in relation with the strategy) for their collaboration with industrial actors and this is a problem related to the top management. According to the responds given by the university researches, there have been observed that they understand well the D2, "barriers" dimension of the collaboration with industrial partners (the scores calculated for D2 are near the value 4, in the case of all investigated universities).

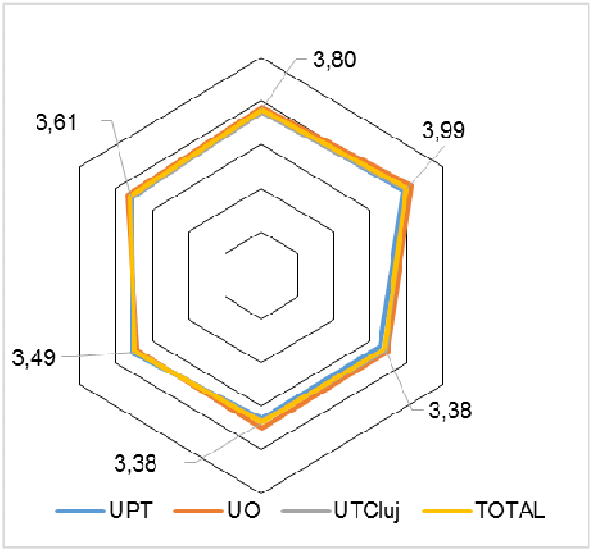

Fig. 4: The university-industry collaboration foot print (research results)

Additional conclusions were elaborated per each university in order to explain the lower scores value for some dimensions:

- Politehnica University of Timisoara researchers do not understand and trust the exiting "channels for the knowledge management transfer" (D3) at the university level. This is an internal communication gap of the organization because UPT research responsible staff do not promote, internally, the facilities created in order to support D3 dimension (i.e. the Office for Innovation and Technological Transfer and the Office for Research Valorisation);
- University of Oradea researchers have express less fear about the "disadvantages" (D5) in their collaboration with industrial partners. They do not consider that this type of collaboration could be in their disadvantage. This is a consequence of the fact that UO is well implicated in industrial collaboration, and the results of such collaborations are well known by the researchers community from academia and the economic environment;
- Technical University of Cluj-Napoca researchers do not have a good perception (they do not realize) on the "benefits" (D4) gained because of their collaboration with industry. This fact is caused by the low perception of the organization benefit (people have low perception of their belonging to the organization). The considered items for the characterization of D4 dimension do not include personal benefits (extra salaries obtained by the researchers through their collaboration with industry).

According to the average profile determined for the three universities, there have been observed low scores for "channels for the knowledge management transfer" (D3 = 3.38) and "benefits" (D4 = 3.38) dimensions and the general causes could be similar with those presented earlier.

4. The Proposed Business Model of University-Industry Collaboration in Open Innovation (UNIinOI)

4.1. The case of UNIinOI at Politehnica University of Timisoara (Romania)

According to the Research Reports in 2012, 2013, 2014 and 2015 there have been underlined that "the research activity carried out by the university was financed through external sources, obtained either from national and international calls for projects, or through agreements with private companies" (economic organizations, mainly located in the West Region of Romania). These information are public, available on the Politehnica University of Timisoara web page (2015). A strength aspect of this organization, according to the last national evaluation is that Politehnica was granted a university of advanced research and education.

The research activity is supported by the infrastructure related to the twenty-five research centres hosted by the university. "The important number of research centres, respectively teams of researchers constituted ad-hoc, on different themes, successfully put in practice the scientific research strategy of the university, within the framework of numerous grants and contracts won by competition. The results of the research are materialized in papers, patents and products, all bringing for the University prestige, as well as important funds".

Collaboration with industrial or other economic partners (institutions, associations, other research institutes etc.) refers to research projects implemented by different national and international partnerships in which the University is part. In addition, Universities research teams that belong to a research centre, can act and establish as a supplier of innovative solutions for industry. Research and collaboration projects can be supported by public funds, both national and international, or private funds awarded by companies.

The key success factors of the university-industry collaboration are considered:

- The university prestige and excellence (95 year of research and education experience celebrated in 2015), including the developed infrastructure for research (25 research centres and a centre for transfer of innovation and know-how);

- The research staff (academic and technicians) expertise that are recognized national and international (proofed by the publications, patents, awards and other relevant honorary degrees that recognize scientific excellence);
- Dissemination actions as scientific events organization, own scientific bulletins publication and books (considered as part of the research and development marketing activity).

4.2. The case of UNIinOI at Technical University of Cluj-Napoca (Romania)

According to the public information on research activity available on the Technical University of Cluj-Napoca web page (2015), the quantity and quality of scientific research that is carried out by the university have a primary role in classifying these at international level, because of the necessity of sustaining and consolidating the activity of the structures of scientific research. The scientific research constitutes an important source of income and of image both for the university globally, and for each researcher. An important aspect of the research field of activity is given to the ongoing support for the process of creating new research structures, and especially for the merging and collaboration process of the research structures into larger units characterized by inter and multi-disciplinary (research platforms, research institutes). This is considered a necessity, clearly demonstrated by the setting up of excellence poles within major impact domains for the social and economic environments. The university has proposed to gain national and international visibility in several major domains of scientific research and technological innovation. To that aim, concrete managerial actions have been taken in order to define the major interdisciplinary domains and to create the necessary research structures.

The main directions of interventions in the research domain that support the university-industry collaboration are:

- Increasing the autonomy and development of the research structures;
- Setting up and modernizing of the high impact research laboratories;
- Establishing an interdisciplinary research institute affiliated to the university,
- Attracting, developing, and maintaining the highly qualified human resource,
- Supporting the publication of the results of research in prestigious journals and conference proceedings,
- Supporting the international conferences with a large visibility, organized by the university,
- Supporting the high performance scientific research,
- Developing the capacity and competence of the university within the technological transfer activity.

The research teams enjoy the freedom of choosing their topics depend on their expertise. However, institutionally, in order to sustain the vision of the Technical University of Cluj-Napoca, that of becoming a pole of international excellence in several domains of research, the following multidisciplinary domains of research are supported, domains reflected by the worldwide, European and national tendencies (as mention in the European Commission's strategy vision to 2020): information and communication technology; advanced materials; advanced products and processes and green energy. The development of the high priority research domains is achieved through the efficient turn to good account of the human, material as well as the financial resources coming from the budget, self-financing and institutional development.

The key success factors of the university-industry collaboration are considered:

- The university research structures and teams prestige (each faculty has groups of research that define research units - 76 research centres and laboratories), described by their infrastructure and research staff for research). Each research units was recognized by the University Senate or the National Council for Research and Development in Romania based on their research results (publications, patents, books) and successful projects implementation;

- The research staff (academic and technicians) expertise that are recognized national and international (proofed by the publications, patents, awards and other relevant honorary degrees that recognize scientific excellence) because of their remarkable research results.

Many professors of the University were involved in the national research and education institutions (in different level of management, including Ministry of Education) and that has been created a great opportunity for the research activity development (including financial approval of the different projects presented in national competitions);

- Dissemination actions as scientific events organization, own journals publication and books (considered as part of the research and development marketing activity);

The successful business model applied for research that assures the increasing of external, additional financial resources of each research unit and researcher.

4.3. The case of UNIinOI at University of Oradea (Romania)

According to the public data available on research on the University of Oradea web page (2015), the University benefits from highly specialized human resources (the university has a multi-specialization offer including art, humanities, engineering, economics, social sciences, medical sciences, theology etc.) so that research activities are a natural consequence, with positive implications for the education processes (transfer of knowledge from research activities to education and vocational training). An important effect of the research activity is attracting funding research (through national, international projects and private founds) for projects and infrastructure development (as a measure of the degree of compliance with the real needs of knowledge and quality of research).

The research activities are achieved through the contribution of university teaching staff and research staff in the framework of different type of collaboration with other universities or economic partners. The main research activities are developed through research projects, competitive system accessed through the research programs of national, European or international, bilateral cooperation projects with institutions in country or abroad or contracted projects with various customers, interested in areas that carry out these activities.

The five specific objectives of the research activities are:

- "Specific objective 1: Research orientation toward priority areas declared national strategy for research and development, focusing on areas where the University of Oradea is well represented;
- Specific objective 2: University of Oradea development as a centre of excellence in relation to the economic, social and community involvement;
- Specific objective 3: Development of the research-development-innovation, University of Oradea;
- Specific Objective 4: Increasing human resources involved in research, development and innovation;
- Specific Objective 5: Improved performance of research, development and innovation."

At the university level, there are recognized 22 research centres (including specialized laboratories with research staff and adequate infrastructure) and a Technology Transfer Centre that support the small and medium size enterprises and other economic organizations to implement innovative technologies through training and consulting activities. The University acts mainly in the North-West Region of Romania and is very active in supporting the trans-border programs between Romania and Hungary. The key success factors of the university-industry collaboration are considered:

- The university research structures and teams/members prestige (by the research entities that exist at each faculty). Each research units was recognized by the University Senate or the National Council for Research and Development in Romania based on their research results (publications, patents, books) and successful projects implementation;
- Funding opportunities and excellent partnerships and alliances in research, that were developed with other universities (from national and international level), industrial partners and other economic organizations;
- The research staff (academic and technicians) expertise that are recognized national and international (proofed by the publications, patents, awards and other relevant honorary

degrees that recognize scientific excellence) because of their research results. The main advantage of the research staff is its diverse competencies and expertise that can easy support trans-disciplinary and inter-disciplinary projects and collaborations;
- Dissemination actions as scientific events organization, own journals and bulletins publication and books (considered as part of the research and development marketing activity).

5. The Proposed Model for the University-Industry Collaboration in Open Innovation

The research analysis done on the three universities has underlined the main elements that should be considered in the proposed model (or framework) for the university-industry collaboration in open innovation, named the UNIinOI model (related to the fourth phase of the research). From the results of the cross-case analysis (done during a focus group with the researchers of the universities involved in this study) of the three universities research activities that can support collaborative projects with industry, it was concluded that a framework model for the effective collaboration should reflect six key areas:

1. A well-established research structure (in the university) that could support efficiently the administrative activities related to the research projects. Romanian university research centres and transfer of innovation centres do not have financial autonomy (they could not act independently from the university financial rules);

2. Providing high quality project management, particularly with regard to objective setting, progress monitoring, effective communication and deploying only trained, high quality project managers to run the collaboration

3. Understanding (continue maintain contact) the specific of the university-industry economic and social environment. Particular attention should be given to identify the trends and specifics of the roles of researchers, post-graduate students (included in the alumni), the specific requirements of industry. In addition, there should be understand the cultural gaps and the divergent interest between industry and university (academic);

4. Develop new partnerships and nurture the existing one by valorising the funding opportunities. Factors such as trust, commitment and continuity of human resources have been shown in the literature to be important to collaboration success. This study has reinforced that these factors enable researchers in having successful collaboration with industry, *in* terms of mutual benefit;

5. Nurture the organizational culture that recognized the power of research and the benefits of it for the university. This could be a *veritable weapon* for the human resources continuous development (research should be a challenge for their expertise recognition) and that will positively impact the university reputation;

6. Establish a coherent strategy of research activity dissemination (of high quality) and support the marketing activities associated with this.

The proposed model (or framework) for the university-industry collaboration in open innovation is represented in Fig. 5. The described framework incorporates all the above mention factors found to have had a significant impact on the perceived success of the university-industry collaboration, taking into consideration the specifics of Romanian universities. Many of the success factors incorporated in the model are also, supported by the research of other workers in the field (as reported in the published literature), therefore providing evidence of the broader applicability of this model beyond the cases examined here.

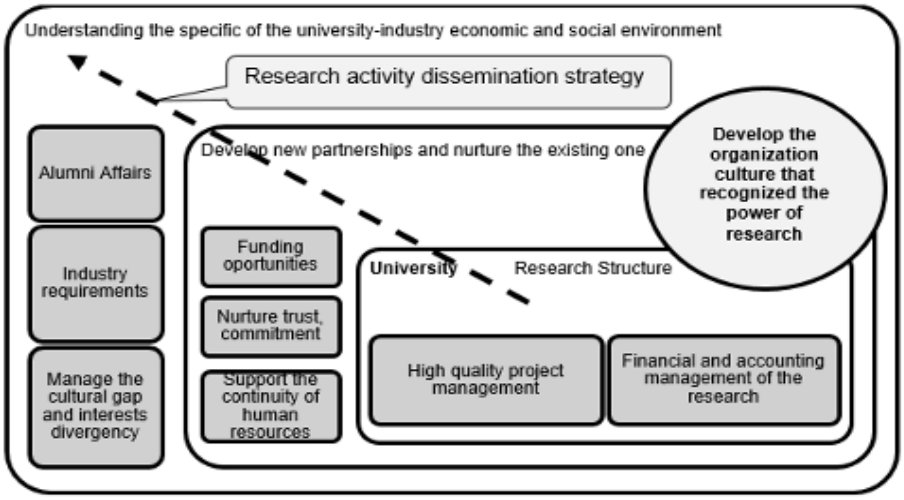

Fig. 5: The proposed model for the university-industry collaboration in open innovation

Finally, this research also identified two new success factors: the role of the lead researcher and the role of postgraduate students (part of the university alumni). These findings are important features of collaborative projects of this kind and as such require attention and careful management if the university-industry collaborations are to be effective and successful.

Conclusions and Future Work

The described approach for the definition of the UNIinOI model, for the university-industry collaboration in open innovation. The research steps were: (1) literature review in the field; (2) definition of the university-industry collaboration ontology (five dimensions and 30 items of characterization); (3) exploiting the ontology for the development of an evaluation process regarding the state of the university-industry collaboration. In this phase there have been shown research results for three cases of three Romanian universities. The purpose of the experiments done was to test and validate the ontology together with the methodological approach; (4) the UNIinOI model definition.

The experimental research has proofed that the research approach of phase 2 and 3 (considered also, as a diagnosis of the actual situation of the university-industry collaboration) could help to identify the strategic direction to be followed by the universities in order to better valorise their potential of innovation with the support and involvement of industrial partners. In addition, the evaluation model could be used to define the universities orientation for business, for profit generation through their research activities develop in partnership with industry.

According to the analysis done, Romanian universities are able to support and they proof the capacity to develop feasible collaborations with industrial partners, because of the key success factors considered (research results):

- The well defines structure of the research and the research entities that exist at the faculty level. In addition, transfer of innovation centres are established and they support the small and medium size enterprises by priority in order to increase their internal innovation process;
- The research staff of high expertise that exist in each university. The actual tendency is to link the research activity to the PhD schools and to engage more and more young researchers in collaboration projects with industry;
- Funding opportunities and excellent partnerships and alliances in research that could assure additional funding for universities and individual researchers, too;
- Dissemination actions as scientific events organization, own journals publication and books (considered as part of the research and development marketing activity).

Among the many important issues raised by this research, some common themes emerged, indicating that a standardized good practice model for the effective management of collaborations between university and industry would provide a useful framework, which could be applied to future collaborative research projects. The proposed UNIinOI model or framework could be useful also, as a mean of systematically improving collaboration management practice and thereby improving the probability of collaboration success.

The next research priority will be the improvement of the proposed model and its testing and validation through different cases of universities' collaboration with industrial and business partners. By this, there should be developed a comparative study between the opinion of the university staff and industry staff, for three distinguish areas in Romania. Furthermore, future researches will be focused on the development of a software product in order to evaluate the level of adoption of open innovation in the framework of university-industry collaboration projects.

Managing the Utilised Agricultural Areas - Key in Obtaining Better Results in Holdings

Phd. Candidate Ramona Dobre
Bucharest University of Economic Studies, No. 6, Piata Romana, Bucharest, 010371, Romania
Corresponding author email: ramonadobre88@yahoo.com

Abstract

The present paper aims to highlight the importance that managing the utilised agricultural area has in obtaining better results in agriculture. There were chosen to be compared eight member states of the European Union, with different areas, different conditions, different level of development and different way of land exploitation. The study investigates the link between the legal status, the size of the holding and their results, by analyzing relevant indicators, and it also formulates, in the conclusion, solutions on how to manage the size of the holding in order to improve the holding activity and its result.

Keywords: utilised agricultural area, legal status, agricultural holding, holding size.

Introduction

Utilised agricultural area of a state reflects the measure in which the agriculture represents an important occupation and income source for the population. The agriculture represents a basic branch of the economy, but an underperforming practicing of agriculture, incapable to supply satisfying results raises problems for some states. As Popescu (2001) mentioned in his paper, "the relation between land property and agricultural exploitation has represented a permanent concern in history".

The increasing interest in practicing the "green" agriculture influences the resizing of holdings. Cunha, (2009), described that "pressures from environmental groups, and from the media and public opinion, were identify as of growing importance, from a low base in 1992 to real considerable in 2003."

Each state influences the size of holdings by the policy applied. The opinion of Floyd, (1995); Harrington and Reinsel, (1995) was "The policy context and policy changes have been identified as important drivers of structural change."

Regarding the exploitation, according to legal status on Eurostat there are found: sole holder holdings, holdings that are legal entity and holding group. The understanding of functionality for each category and the measure in which are found in each state ant the results they have is very important. Also the physical size of agricultural holdings in each state justifies the results obtained in agriculture. In his work Ciaian, (2010), mentioned that" Amongst the productive factors, land is the one which most often limits farm development and which is most directly applicable as an indicator of farm size" The decisions of Common Agricultural Policy (CAP) also influence the holdings size. Bartolini, Viaggi concluded that
"CAP payments seem to play a role, both affecting exist strategies and preferred farm size".

The orientation towards other types of activities non-agricultural related in rural area had an impact on the holding sizing. Lange (2013) concluded that "farm size and the share agriculture of household income are higher than the impact of landscape features".

Understanding how to manage the utilised agricultural area, adjusted to each state characteristic, in order to generate the best results is a progress that can help the development of rural areas, as long as agriculture still represents a big part in the rural area activities.

Materials and Methods

The study is conducted by calculating, analysing, comparing and interpreting data, such as utilised agricultural area, average surface of an agricultural holding, legal status of the holdings, standard output. The indicators were selected with the purpose of demonstrating how important really is managing the utilised agricultural area in development and results. The data utilised are extracted from EUROSTAT data base and follows eight member states of the European Union – Belgium, Bulgaria, Germany, Spain, France, Italy, Netherlands and Romania during the period 2005-2013. There were selected states with different surfaces, different utilised agricultural area, different conditions, and different level of development in order to see their evolution concerning the results obtained.

Utilised agricultural area

It is very important to understand the potential given by the utilised agricultural area in the eight member states of the European Union submitted to analysis. For this purpose there are presented the agricultural land surfaces of each state and the evolution between 2005 and 2013.

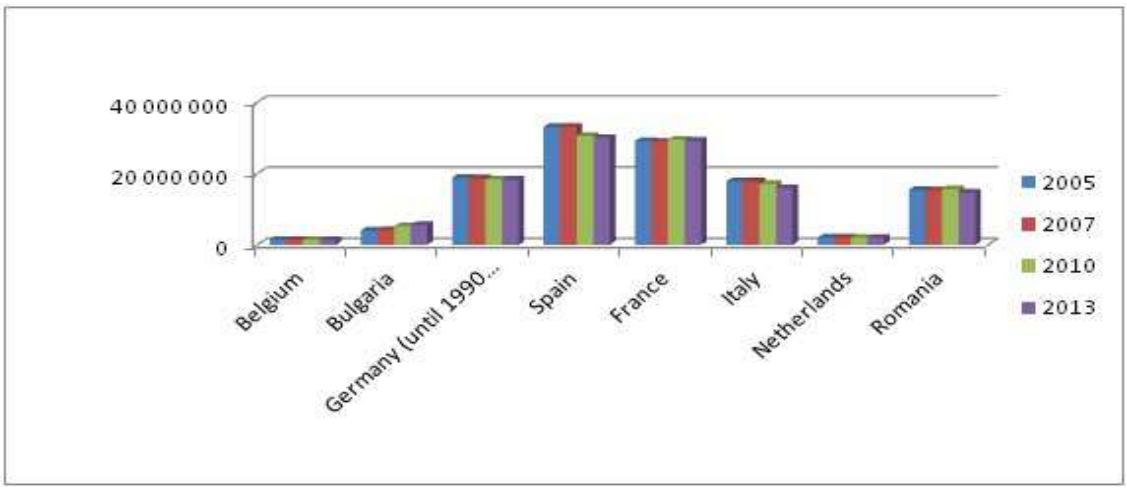

Fig 1: Utilised agricultural area(ha)

The chart no. 1 presents the utilised agricultural area measured in hectares in Belgium, Bulgaria, Germany, Spain, France, Italy, Netherlands and Romania in the years 2005,2007,2010,2013.

By analyzing the chart it may be concluded that from all the states presented, the smallest utilised agricultural area is held by Belgium while the state with the largest utilised agricultural area is Spain. The explanation of this conclusion may be found in the total surface of each state. Therefore, if it is considered that in the year 2013, in Belgium 1 350 200 hectares of 3 052 800 (44,23%) represents agricultural land, in Bulgaria 5 608 980 hectares of 11 099 400 (50,53%) are intended to agriculture, in Germania 18 305 150 hectares of 35 734 000(51,23%), in Spain 30 042 210 hectares of 50597000(59,38%), in France 29 264 400 hectares of 63283360 (46,24%), in Italy 15 933 790 hectares of 30 207 300(52,75%), in Netherlands 2 008 870 hectares of 4154000(48,36%) and in Romania 14 661 380 of 23839100(61,50%), it can be noticed that the utilised agricultural area of each state held an important percent in total surface of the concerned state. In the Romania's case the percent of 61,5 may point out the fact that a high number of persons are occupied in agriculture, that there are a high number of subsistence and semi-subsistence holdings and also that there is a lack of available jobs in others fields.

It can be noticed that during the analyzing period 2005-2013 there are oscillations regarding the number of hectares of utilised agricultural area, but the increases and / or decreases were not major. While in Spain, Germany and Italy there was an obvious reduction, Belgium and Netherlands tended to maintain the values of the utilised agricultural areas and Romania and France showed both decreases and increases. The explanation in this regard is found in changing the land destination, decreased/increased interest in practicing the agriculture, unfavourable conditions for practicing the agriculture. The agricultural surface of a state reflects the degree to which the agriculture as branch is important to the economy.

Utilised agricultural area per capita

This indicator reflects how many hectares of agricultural area exist per capita in each analyzed state and its evolution between 2005 and 2013.

Table 1: Utilised agricultural area per capita(ha/capita)

State/year	2005	2007	2010	2013
Belgium	0,13	0,13	0,13	0,12
Bulgaria	0,35	0,40	0,60	0,64
Germany	0,21	0,21	0,20	0,21
Spain	0,57	0,56	0,51	0,50
France	0,44	0,43	0,43	0,42
Italy	0,22	0,22	0,22	0,20
Netherlands	0,12	0,12	0,11	0,11
Romania	0,65	0,65	0,66	0,65

Source: Own calculation based on EUROSTAT data

The values for this indicator were obtained following a simple calculation by dividing the entire utilized agricultural area to total population of each state. Analyzing the results obtained allows to conclude that between 2005 and 2013 there were no major changes in the analyzed states except Bulgaria which went from 0,35 ha/capita to 0,64 ha/capita, it almost doubled its value. Romania has the highest value of this indicator, in 2013, 0,65 ha/capita, followed by Bulgaria, Spain with 0,50 ha/capita(a decrease from 0,57 ha/capita in 2005), France with 0,42 ha/capita(a decrease from 0,44 ha/capita in 2005), Germany and Italy have approximately 0,20 ha/capita and Belgium and Netherlands 0,12 ha/capita. Worth to be mentioned is the fact that the evolution of this indicator is highly influenced by giving other destination to the land and also by an increase/decrease of population.

Average surface of an agricultural holding

In the table no. 1 there are presented the average surface of an agricultural holding in Belgium, Bulgaria, Germany, Spain, France, Italy, Netherlands and Romania and also its evolution between 2005-2013.

Table 2: Average surface of an agricultural holding(ha/holding)

State/Year	2005	2007	2010	2013
Belgium	27,47	29,27	32,32	35,76
Bulgaria	7,51	8,29	14,20	22,05
Germany	48,33	50,44	61,47	64,22
Spain	30,67	31,77	30,93	31,13

France	51,45	54,90	57,25	61,97
Italy	10,30	10,62	10,54	15,77
Netherlands	24,87	27,04	27,91	29,77
Romania	3,62	3,88	4,07	4,04

Source: own calculation based on EUROSTAT data

By analyzing the data of the table no. 1 it can be noticed that the states under analysis had a generally ascending trend regarding the average surface of an agricultural holding, except Spain where the average surface decreases from 31,77 hectares to 30,93 hectares between the years 2005-2013, Italy where the average surface of an agricultural holding diminishes from 10,62 hectares to 10,54 hectares and Romania where the average surface of an agricultural holding reduces from 4,07 hectares to 4,04 hectares. The explanation of this situation is found in the economic crisis in 2008 that stroke all the activity sectors, but also through the reducing of the entire utilised agricultural area, the reorganization of the agricultural holdings and by the politics concerning the agriculture formulated and implemented by each state.

It can also be noticed the fact that there are big differences between average surface of the agricultural holdings in the analyzed states. Therefore, while Germany reached in 2013 an average surface of agricultural holding of 62,22 hectares, Romania registered in 2005 only 3,62 hectares per holding. The explanation are found in the degree of economic and social development of each state, so regardless the utilised agricultural area held, the developed states had higher values of the average surface of agricultural holdings. In the year 2013 France and Germany had an agricultural holdings average surface of 61,97 hectares respectively 64,22 hectares; Spain, which has the biggest utilised agricultural area of the analyzed states, had 31,13 hectares per holding. States whose agricultural potential, in terms of utilised agricultural area was small, compared to the other analyzed states, the Belgium and Netherlands case, had agricultural holdings with 35,76 hectares respectively 29,77 hectares as average surface. Italy had an agricultural holdings average surface of 15,77 hectares. This situation may be explained by "the separation" of Italy: the north side which is industrialized and not based on agriculture and the south side which is less industrialized and where is practiced more agriculture. Bulgaria and Romania the second-last states to became members of the European Union had an agricultural holdings average surface of 4,04 hectares respectively 22,05 hectares in 2013. Remarkable is the ascent of this indicator in Bulgaria, in 2005 the average size was only 7.51 hectares and by 2013 it reached 22.05 hectares, an increase of nearly 3 times higher compared to 2005. Romania has also registered an increase in 2013 compared to 2005 but this increase is very small. Romania held a high potential in terms of utilised agricultural area, but registered the lowest value of the agricultural holdings average surface, compared to the states analyzed. The main cause of this situation is represented by the excessive fragmentation of the agricultural land, which determined a high number of holdings, due to politics and laws adopted beginning with the year 1991.

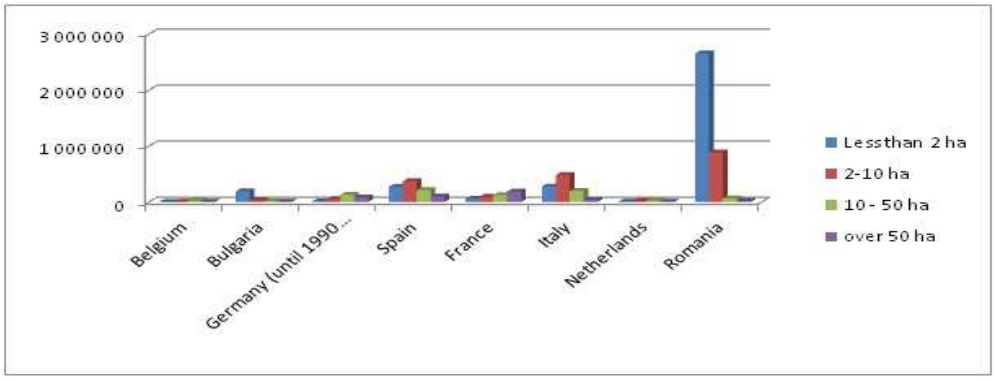

Fig 2: Physical size of holdings, 2013

From the chart no. 2 it may be observed that regarding the physical size of the agricultural holdings in Romania there were, in the year 2013, by far the highest number of agricultural holding with less than 2 hectares. It can also be the case of Italy and Bulgaria but not at the same level. The chart highlights clearly the fact that Romania had in 2013 a huge number of agricultural holdings and the majority were holdings with the size under 2 hectares. States as Belgium, Germany, Netherlands and France presents a homogeneous situation of the agricultural holdings number, concretely they had they have the number of farms depending on the physical size at about the same level. In Spain and Italy there were predominant holdings with up to 50 hectares. The explanation of this situation is found in the historical evolution of each analyzed state, the existence/ inexistence of traditions in practicing the agriculture, the reason of practicing the agriculture (hobby, business or need). For instance in the Romania's case the agricultural land exploitation remains for a part of population, from rural areas, the only source of products and/or income where there is a surplus in production which reaches the market.

Regarding the legal status of the agricultural holdings, according to EUROSTAT, there are distinguished: sole holder holdings and holdings that are legal entities.

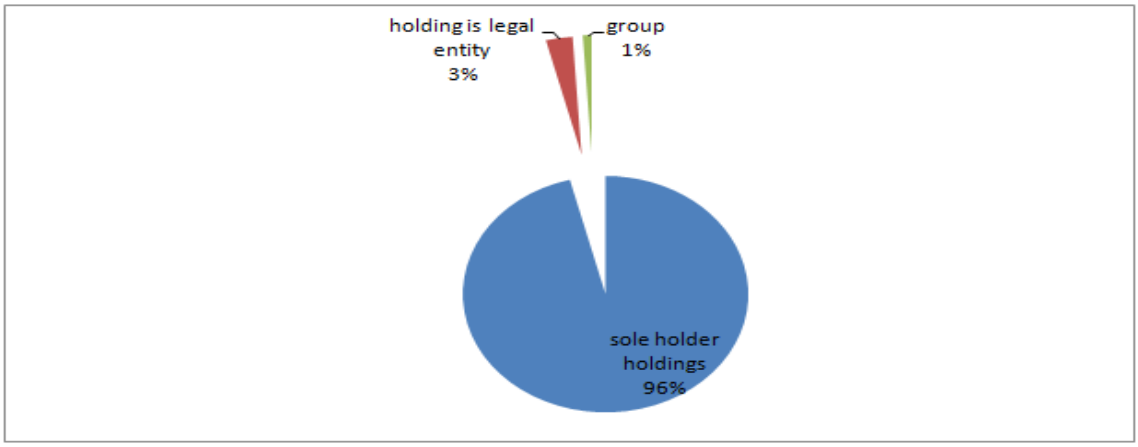

Fig 3: Share of holdings according to legal status, at the eight analyses states level, 2013

Regarding the legal status of the agricultural holdings, it can be observed, that in the year 2013, at the level of the eight states analyzed, the sole holder holdings predominate with 96%, only 3% holdings are legal entity and only 1% is a group holdings. The situation is explained by the nature of the activities itself, which take place within an agricultural holding and by the fact that a high number of the holders are in fact the owners of the lands that they are exploiting. A big contribution to the 96% is brought by Romania, which, as we established by the precedent analyse of chart no.2, has a high number of agricultural holdings with less than 2 hectares; these holdings are, mainly, not legal entities and they do not belong to a group holding. In principle due to reduced physical size, they are semi-subsistence or subsistence holdings, therefore contributes significantly to the 96 percent owned by sole holder holdings.

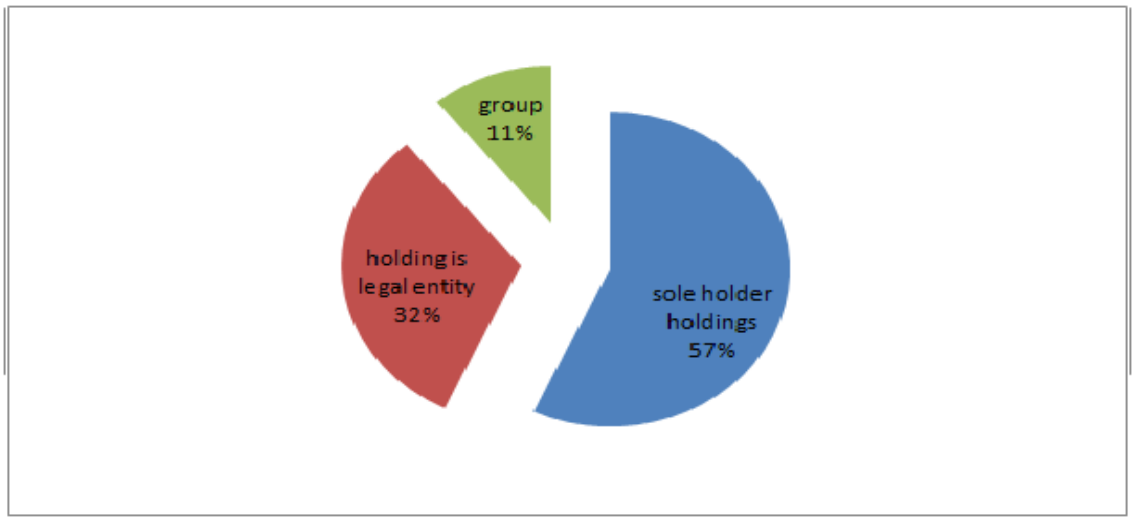

Fig 4: Utilised agricultural area distribution according to legal status, for the eight analyzed states, 2013

In terms of surfaced occupied by the agricultural holdings, from the eight states under analysis, according to their legal status, in the year 2013, it can be observed by analyzing the chart no. 4 that 57% of total utilised agricultural area is occupied by sole holder holdings, 32% is occupied by holdings that are legal entities and 11% is occupied by group holdings. Analyzing in the same time the cart no. 3 regarding the number of holdings according to their legal status it can be concluded that at the level of the eight states under analysis, in the year 2013, 93% of total agricultural holdings used 57% of total utilised agricultural area, 3% of total agricultural holdings used 32% of total utilised agricultural area and 1% of total agricultural holdings used 11% of total utilised agricultural area. Therefore it can be established that the agricultural holdings with small physical size are part of sole holder holdings.

In order to better understand the conclusions formulated following the chart analysis, there will be interpreted data regarding the average physical size of an agricultural holding in terms of its legal status, from the eight states submitted to comparing, and also their evolution during the period 2005-2013.

Table 3: Average physical size of an agricultural holding in terms of its legal status

	Average physical size of a holding that is legal entity				Average physical size of a sole holder holding			
State/year	2005	2007	2010	2013	2005	2007	2010	2013
Belgium	33,06	34,55	38,01	39,22	26,43	28,11	30,99	33,94
Bulgaria	454,85	479,5	503,91	486,02	2,40	2,95	4,83	7,11
Germany	610,88	573,04	584,03	554,28	32,04	33,42	40,60	42,56
Spain	150,02	141,68	118,87	115,05	16,65	17,19	17,86	17,95
France	85,49	88,5	92,59	97,12	32,20	33,25	32,19	33,27
Italy	79,63	106,52	79,14	87,24	6,12	6,64	7,17	10,88
Netherlands	24,95	23,57	24,51	25,08	23,70	24,86	25,97	27,53
Romania	263,13	270,44	190,77	207,49	2,15	2,29	1,95	2,02

Source: own calculation based on EUROSTAT data

It is observed, according to the date in table no. 3 that both average surface of sole holder holding and average surface of holding that is legal entity presents oscillations. States that do not have a tradition in practicing the agriculture, such as Belgium and Netherlands, don't presents significant differences regarding the average surface of agricultural holdings in terms of their legal status. In Belgium, in 2013, the average surface of a holding which was legal entity was 38,01 hectares and the one of sole holder holding was 33,94 hectares; in the Netherlands of the same year 25,08 respectively 27,53. In Spain the average surface of an agricultural entity that was legal entity decreased from 150,02 hectares in 2005 to 115,05 in 2013 and average surface of a sole holder holding increased from16,65 hectares in 2005 to 17,95 hectare in 2013.

In Bulgaria, Germany and Romania is noticed that the differences between averages of the agricultural holdings are very big. If the size of an agricultural holding that is legal entity, in 2013, in Bulgaria was 486,62 hectares(even if during the period 2005-2015 registered oscillations, average size is higher compared to 2005 when it was 454,83 hectares), in Germany was 554,28 hectares(during the entire period 2005-2013 the average size of the holding decreased, in 2005 was 610,88 hectares) and in Romania was 207,49 hectares(even if oscillates between 2005-2013, average size is smaller compared to 2005 when it was 263,13 hectares), the average size of a sole holder holding, in 2013, in Bulgaria was only 7,11 hectares (a remarkable increase compared to 2005 when it was only 2,40 hectares), in Germany it was 42,56 hectares (an increase compared to 2005 with approximately 10 hectares) and in Romania it was only 2,15 ha (worth to be mentioned that there were not registered significant modification during the period 2005-2013, average size being maintained at approximately 2 hectares. Also, in Italy are observed differences of over ten times between the average physical size of a sole holding holder and a holding that is legal entity. The average size of a holding that was legal entity was 87,24 hectares in 2013 and the average size of a sole holder holding was 10,88 hectares. In France the average size of a holding that was legal entity increased during the entire period 2005-2013, from 85,49 hectares to 97,12 hectares, in the same period sole holder holding maintains its average size around 32-33 hectares.

The explanation of the situation presented by analyzing the date in table 4 is found in the property and exploitation structure of each state, and also in the politics concerning the agriculture elaborated and implemented by each state, the motivation in practicing the agriculture, the utilised agricultural area of each state. For instance in Romania, the explanation is found in adopting and applying an incomplete and faulty law, more precise Law 18/1991 regarding the allotment and re-allotment of agricultural land owners. This law leaded to a massive number of small sized agricultural holdings. The failure of remediating this law, through Law 1/2001 is reflected directly on the situation during the period 2005-2013.

Results obtained in agriculture

There will be followed the results obtained in agriculture by analysing the standard output overall, between 2005-2013, and the standard output obtained per holding and per hectare in 2013.

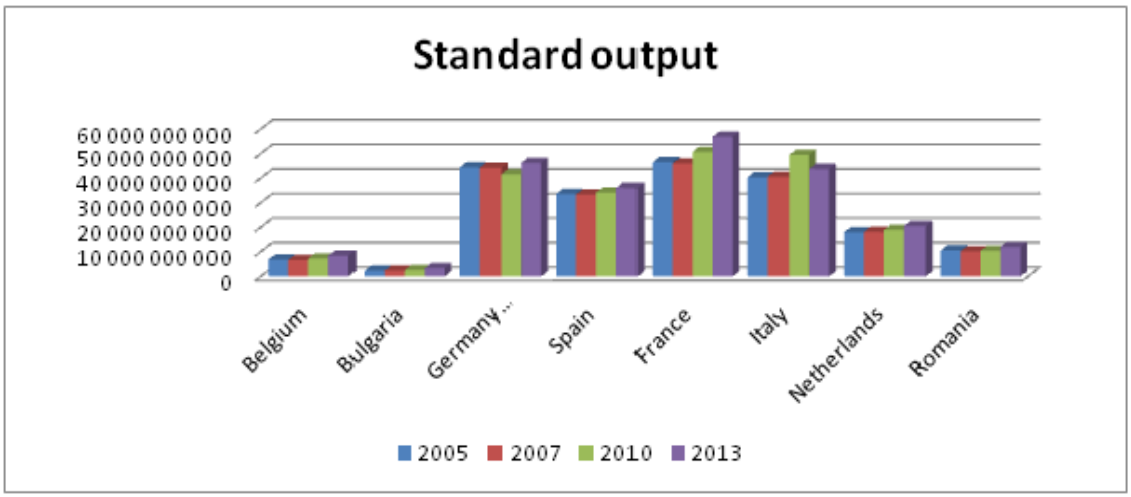

Fig 5: Standard output(euro)

The analysis of standard output, counted in euro, presents oscillation, in all states, during the period 2005-2013. Germany, France, Spain and Italy had the highest values of this indicator during the entire period of analysis. This situation is explained by the high potential that they have in terms of utilised agricultural area but also the manner of the exploitation. It is observed that, although, Belgium and Netherlands, as we previously analyzed, are states with small utilised agricultural areas but with medium average size, both for sole holder holdings and legal entity have standard output values higher (Netherlands) or close (Belgium) compared to Romania that has an utilised agricultural area much larger. Bulgaria has the smallest value compared to the seven other states. Te efficiency in exploiting the agricultural land is the explanation of this situation.

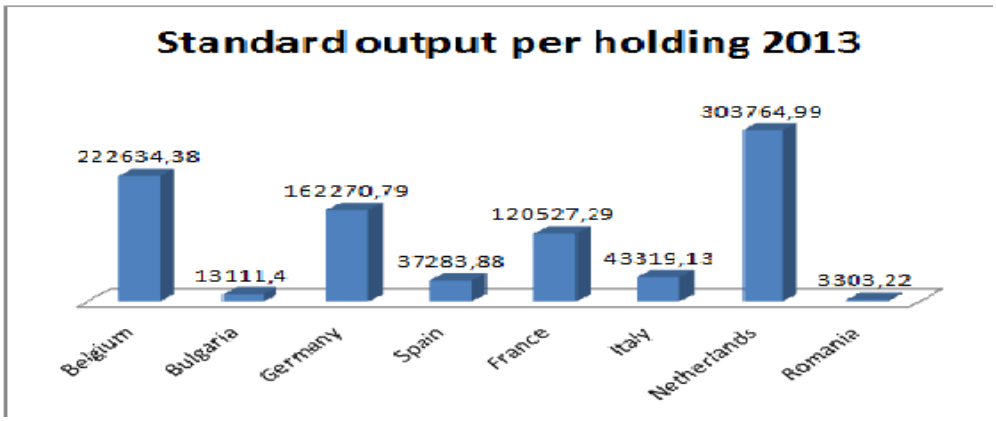

Fig. 6: Standard output per holding 2013

By analyzing the chart no.6 it's noticed that states with small UAA, as Belgium and Netherlands, registered the highest standard output 303764,99 euro per holding respectively 222634,38 euro per holding. States with high potential in terms of UAA have modest results compared to Belgium and Netherlands; Germany registered a standard output of 162270,79 euro per holding, France 120527,29 euro per holding, Italy only 43319,13 euro per holding, Spain 37283,88 euro per holding. The lowest standard output is registered by far in Romania and is only 13111,40 euro per holding, this way being inferior to Bulgaria which registered 13111,40 euro per holding. The explanation that higher results are registered in states with the smaller UAA is found in the holding structure and its manner of exploitation.

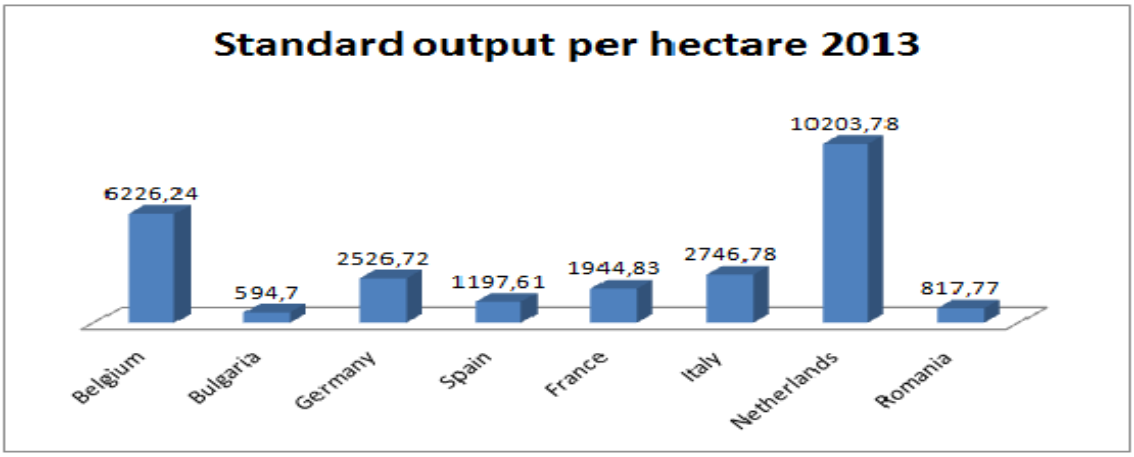

Fig. 7: Standard output per hectare 2013

The analysis of standard output per hectare, for the eight state, in 2013, changes the ranking, Bulgaria takes over the last place with 594,70 euro per hectare, behind Romania which had a standard output of 817,77 euro per hectare. The first places are forwards held by Netherlands and Belgium with 10203,78 euro per hectare respectively 6226,24 euro per hectare. Italy has a better result on hectare than the one on holding an it reaches 2746,78 euro per hectare. Germany had a standard output of 2526,72 euro/hectare and France 1944,83 euro/ha.

The analysis of standard output per agricultural land hectare highlights the fact that despite the total utilised agricultural area better results are obtained through an appropriate holding structure and by efficiently exploitation of the land using modern techniques and technologies. It is obvious, that the state through its politics may contribute to the results by giving financial support in developing the holdings and by educating, encouraging and guiding of holders.

Standard output per hectare in terms of legal status 2013

In order to better understand the results obtained within the holding it is also analyzed the standard output per hectare by legal status in 2013.

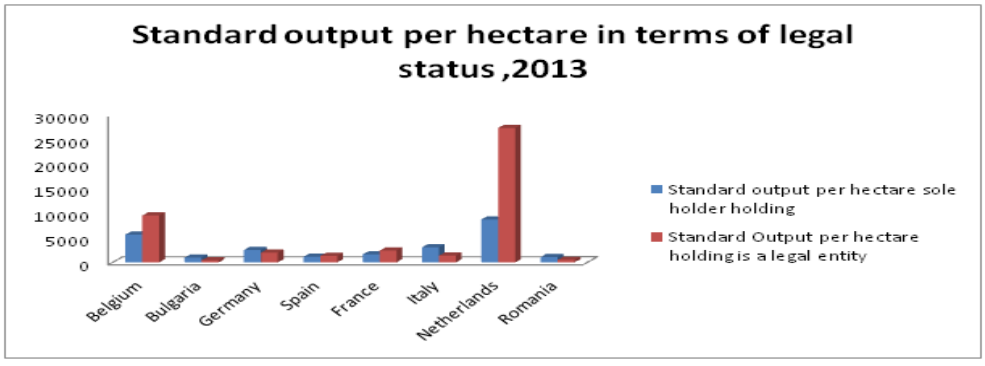

Fig. 8: Standard output per hectare in terms of legal status, 2013(Euro/ha)

The chart indicates the fact that in the states with a high value of the standard output per hectare and holding (as shown in the previous charts) such as Belgium and Netherlands, the standard output per hectare is higher in the holdings that are legal entities. Not at the same level of difference but in the same situation is found France and Spain. Bulgaria, Germany, Italy and Romania have better results per hectare in the sole holding holder. The results are explained by the number of holdings, their

physical size and the manner of exploitation. Correlating the data from this chart with the data from Table no. 3, average physical size of an agricultural holding in terms of legal status, it can be observed the fact that even if the average physical size for sole holder holding is way bigger than the average physical size of sole holder holdings there are obtained better results per hectare in the case of sole holder holdings (Bulgaria, Germany, Italy, Romania; the only exception is Spain). The equilibrium in managing the utilized agricultural area from Belgium and Netherlands reflects the best results, compared to the other analyzed states, both in terms of standard output per hectare in sole holder holding and holdings that are legal entities.

Conclusions

After analyzing the indicators it may be concluded that the potential, in terms of utilised agricultural area of each states, loses its importance if is not properly valued.

It can be noticed that although some states have large utilised agricultural area, as in Romania's case, that the results obtained both on holding and also on hectare are reduced. A high importance in obtaining these results is held by the exploitation structure. The physical size of the agricultural holding, along with their legal status also has an important influence on the results.

The manner in which the utilised agricultural area are exploited has a direct impact on labour force needed and used, both by holding and hectares number that are in the responsibly of a worker. In the holdings with small physical size, which in the most of the cases are sole holder holdings, the labour force employed directly by the holding is basically inexistent, due mainly to the lack of financial resources. Therefore the small sized holding along with insufficient labour force, chemisation, and mechanisation determines poor outcomes.
A rational exploitation, in which a bipolarisation of the agricultural holding regarding the average physical size in terms of legal status, as in Netherlands and Belgium case which proved better results both on holding and per hectare.

It is also noticed the fact that the results of the agricultural land also depends on the development degree of each state. States as Romania and Bulgaria, which are, compared to the other states analyzed, less developed from economical point o view, have lower results, due mainly to the lack of the financial means that are so needed, on one hand in research, which could contribute to the improvement of land exploitation by reorganizing the exploitation structure and on another hand in investments towards agricultural holdings modernization.

Along with the manners of structuring and exploiting of the agricultural holdings, the results are also influenced by other factors such as the quality of the soil, climatic conditions which dictates the mechanization and chemisation necessary.

The indicators analyzed within the present study proved that although the state compared have different areas, different utilised agricultural areas, different pedo-climatic condition, managing to maintain an equilibrium regarding the average physical size of the holding is the key in obtain better results. This conclusion is explained by the fact that states as Belgium and Netherland, although they have inferior condition compared to the other analysed states, due to their positioning, total utilised area, surface, climate and soil, their results in terms of standard output is directly justified by the situation in which there are no big differences between the physical size of sole holder holding and holding that is legal entity.

In order to obtain better results the holdings must, first of all, be resized. At a state level a bipolarisation of the holdings in terms of size will always cause problems, there will always be a huge difference between the small and the large holdings if we follow their results. Each state must formulate policies and laws meant to improve the results for both small sized and large sized holdings, no matter their legal status.

Abstract

Before now, enterprises were concerned to sell at the best price, obtaining the highest profit as offering the best product, due competitors were at the same circumstances or just a few respected their market areas. However, at this time of dynamic changes, the phenomenon of globalization of the economy involves it every day with more force in the global ambits, upsetting all structures that give sustenance the existence of the organizations whether are big or small, with some or a lot of development, drawing a complex, more diverse and fragmented environment; product of several and complementary events in recent years. This phenomenon has allowed to support this research, which addresses the issue of micro, small and medium-sized Mexican companies, since their background, to the effect of implementation of tax reforms that were settled since January 2014; specifically in the financial aspect of Microenterprise Sector. In recent years the Mexican tax system has been changing without stop, and these organizations have been immersed in its economic and social structure, due to tax changes that have frequently experienced.

Keywords: Tax reforms, microenterprises, culture fiscal

Introduction

It is worth to mention that the constant changes in the tax laws establish challenges that cannot be accomplished, specifically talking of the tax regime Incorporation (RIF) just to mention some, this great group of taxes which targets such organizations, which are difficult to meet because of the great number of these, by the lack of economic capacity and ignorance in the use of technology. .

Quoting to Cuevas (2007: 25) says that microenterprises are continually in the national debate because are considered the main sector of the Mexican economy, however, 80% fail within their first four years of work. A possible cause of such ephemeral existence can be due to lack of training and appropriate advice in the field of administration and enforcement of tax obligations or because of requirement of financial support for their growth, permanence and sustainability.

In the same way and quoting Suarez (2007: 27) comments that microenterprises conform most of the economic sector of Mexico, and its strengthening will result in a national well-being.

Effect tax reforms 2014

Observing the described above, and the aspiration to contribute to the study of these kind of companies, the central question guiding this research is: What is the financial and technological impact of Microenterprise commercial sector resulting from tax reforms of 2014 and what are its characteristics and benefits?

In the exploration of knowledge referring to the mentioned problem, this research aims to achieve the following objective: study, know and identify financial and technological impact of Microenterprise commercial sector resulting from the tax reforms of 2014 and identify what are its characteristics and benefits for these companies.

Analysis of Mexican microenterprise

It is really important to mention that microenterprises in México must continue struggling to survive, to the continue impact of repeated changes to tax laws and as a result of this problem, however are immersed in the onslaught of globalization.

Against this background therefore we started from the following hypothesis: The RIF stops the growth of the commercial sector Microenterprise, fostering uncertainty, inequality and injustice which stops their development and presence in the market.

The results formed in this research, express considerable importance of the need to use a mixed methodology to investigate the feeling and acting of micro entrepreneurs in fiscal aspect that contributes to support microenterprises in the commercial sector in solving their problems, looking forward have access to better financial possibilities and business stay.

In this way, Regalado mentions in http://www.eumed.net/libros/2007b/274/31.htm), that microenterprises, are of particular importance to national economies, not only for their contributions to the production and distribution of goods and services, but also for the flexibility to adapt to technological change and great potential for job creation. Represent an excellent way to boost economic development and a better distribution of wealth.

Angeles (2007: 16) and Cereceres (2004: 37), says that in Mexico, microenterprises represent a very important part both in the economic context and in its employment generation, besides these companies establish by the desire for economic improvement of some people (businessmen) who become independent in this way

With the study focused on Microenterprises of the commercial sector in Mexico, we can understand and identify the problems that companies have following the imposition of the new tax regime and how to establish recommendations to be implemented in order to cope with the impact on the Microenterprise finance facing the commercial sector.

Effect of globalization in microenterprises

There is a big gap between rich and poor countries, and if it is wanted to reach a "globalization" there must be equality talking about fair competition where everyone has opportunities of participation and economic growth.

The Mexican tax system is very complex, and the tax reform should contemplate an injection of simplicity. It should also consider the removal of several special treatments to various sectors of the economy, because as we have already seen that there are many Mexicans pay a lot of taxes, while others pay just a little or pay nothing.

Tax evasion is very high. A lot of efforts must be made to reduce it, including actions of administrative simplification, creating incentives to increase the payment culture, and strict accomplishment of laws. In addition, penalties for evasion should be increased. Finally, there is still corruption in the tax collector department of the government, a practice that should be attacked more firmly.

Taxpayers should be able to notice that their taxes serve to improve the standard of living of all Mexicans. It is worth to take up two essential concepts: transparency, which implies clarity in the allocation and use of public resources; and the accountability, suggesting that in order to pay taxes in a conscious way, impunity must disappear.

This project is funded by the Universidad Autónoma de Sinaloa in Mexico through the Program Development and Research Project Support (PROFAPI 2014).

Abstract

SMEs play an important role in the country's economy, due to their high number. The legislation currently in force and the country's economic instability and the effects of recession have had an impact on SMEs, they being resisting a short time on market or going into decline.
This paper presents the situation of SMEs nationwide and tries, in the county of Sibiu to help these organizations by identifying the problems they face and find solutions in order to turn them into productive and profitable entities.

Keywords: strategy, strategic planning, SMEs, market, management.

Introduction

The term for „strategy" comes from the Greek word „strategya". This term was first used by the Greeks in the army and signify a group of activities related to the preparation and carrying the battle to ensure victory. The French took the term „stratégie" in the army too, with the same meaning. By the mid-twentieth century this term was taken over and used in US companies on the grounds that in business „any market is a war" and the competitive battle to secure the survival and development of the company must be based on a strategy.

According to Punt (2015) strategic planning can be defined as a process/ management tool that allows an organization to focus on efficient resource alignment of its mission and vision.
These two concepts presented above represent the essential points in the present work, which aims to analyze the situation of SMEs in the region of Sibiu county and meet the problems they face.

General information on the current situation of SMEs in Romania

Romanian economy is supported by the activities of SMEs and large companies, especially those with majority foreign capital, but also those with state capital. Although they have a numerical weight of more than 99.7% of the total number of enterprises, a research study by Anghelache (2015) showed that the SMEs influence on economic development of the country is being much lower (approx. 55-56% of GDP).

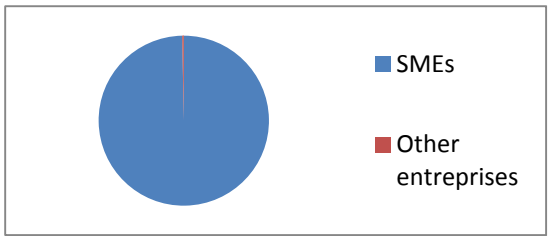

Fig. 1: Share of numerical enterprises in Romania

Autochthonous SMEs are considered by Nicolescu (2012) more "bundled" with large companies when external factors influence (as was proved during the recession of 2009-2011) strongly affects overall economic activity and social stability.

Most companies in Romania started as a family business, based on a minimum knowledge of the people involved in running the business. Many of these people do not have a sufficient amount of knowledge in management or marketing, and the company does not have sufficient financial resources to develop the business by running marketing campaigns or product promotion.

Nicolescu (2012) mentioned that technical and educational level of most SMEs allow their economic survival, but the chances of attracting, hiring and keeping in business of skills, particularly managerial, technical and market are still quite limited. Many enterprises have not set targets for market penetration and growth in market share, never considering the need to attract and hiring specialists, eg in the quality of the product or in promoting them on the market, focusing usually on achieving production and employer's ability to manage / maintain the business "afloat". Relevant statistical data show that about 57% of current microbusinesses are subsistence businesses that would ensure a certain standard of living only to the business owner and his family.

Case study: The main problems of SMEs in the county of Sibiu and their direction of development in the coming years

From the figure below, it can be seen that in the county of Sibiu there is a relatively high share of SMEs compared to the rest of the country, which makes the conclusiveness of this study to have a high veridicity.

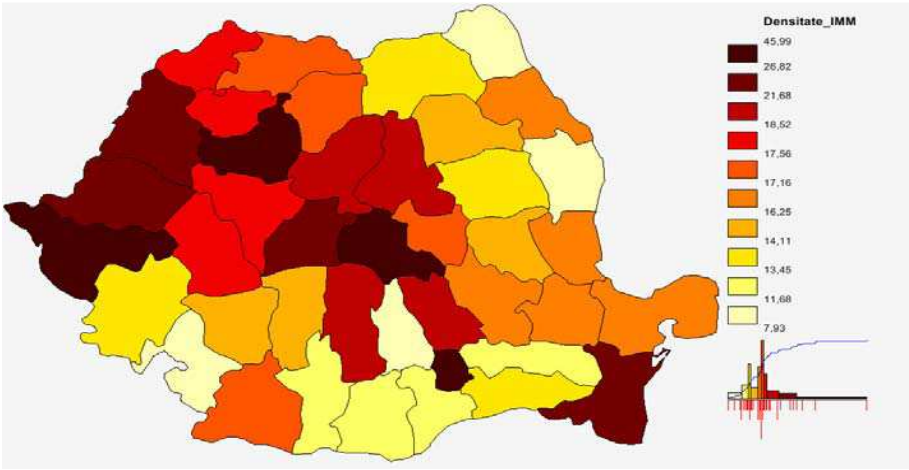

Fig. 2: The radiography SMEs at territorial level
Source: http://www.aippimm.ro/

To obtain the data this study used a quantitative method of research, respectively the investigation based on survey, which has been based as instrument a questionnaire of ten questions, applied on a sample of 384 respondents, managers of SMEs in the Sibiu county . This sampling method is a proportional stratified one according to two variables of characterization: SMEs size and scope of their activities, the research results being guaranteed with a probability of 95% and an error of $\pm$ 5%.

To the question entitled *"What are the problems facing the organization you are part of?"* the answers were as follows:

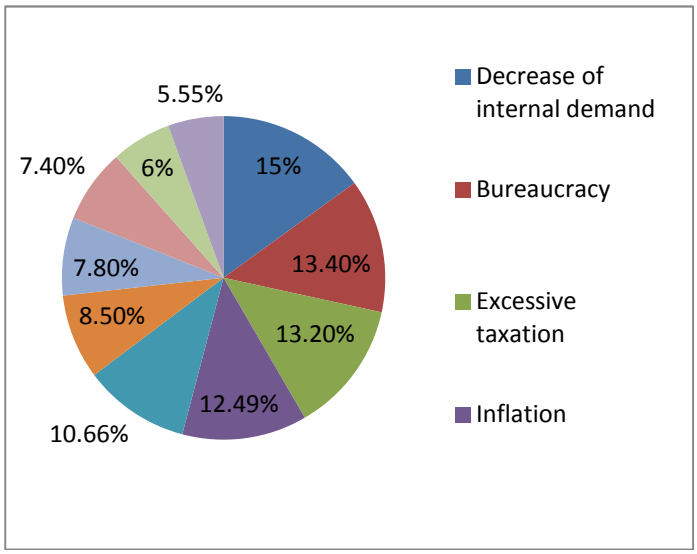

Fig. 3: Main problems of SMEs

Analyzing the answers given to the question: " What are the main critical factors for the economic activity of SMEs?", the most relevant responses were:

a) adequate capitalization of the business according to the evolution stage of the organization and also the foreseeable prospects for its development;
b) enterprise retechnologisation and increasing its capacity to attract and storage within the enterprise the individual creative talents;
c) reducing barriers market entry for new businesses, respectively, barriers to exit from the market of companies proven to be non-viable (with very negative financial results thereof);
d) strengthening networks of entrepreneurs and disseminate relevant market information among them;
e) company business internationalization.

Also, surveyed managers consider several priority directions that can help this segment to grow:

- providing a stable and predictable legal framework for business, with improved aspects of reducing bureaucracy and fiscality;
- increase the amounts allocated to programs for establishment and development of SMEs, which will ensure the creation new jobs and GDP growth in the next period;
- relaunching investment process through: diversification of services offered to re-launch SME financing;
- measures to stimulate SMEs: gradual taxation for SMEs start-ups - tax exemption in the first year, 50% reduction of the corporation tax in the second year with a requirement to ensure the functioning of the company on lasting a minimum of three years after the completion of facilities; improving the legal framework of state aid schemes with the criteria for granting modification to make them fully accessible to SMEs;
- development of SMEs from Romania by supporting the distribution and comercialization of their products, instituting mandatory for large retail chains to provide a minimum retail space (30%) for the presentation and sale of products made by traditional and local SMEs;
- improving SME access to finance through: simplifying procedures, increasing the absorption of structural funds; improved regulation exempting tax on reinvested profit; increase SME access to public procurement; establishment, according to European practice, the mediator of loans to SMEs in the county after the French model;
- the inventory of full fiscal taxes and permits, authorizations and licenses in force, including procedures to achieve them, which is accessible online and which constitutes the support of

reducing by at least 10% of them and simplify administrative procedures on the establishment and operation of businesses and reduction of taxation;
- improving enforcement regulations for budgetary debts, by unblocking of bank accounts of SMEs and creation of a system of rescheduling amounts, by withholding up to 30% of monthly income, without affecting the payment of salaries and current activity.

Conclusions

The importance of SMEs to economic development in the county of Sibiu, arising from the following features of these:

- provide new jobs;
- fosters innovation and flexibility;
- is being constitute practical in places where staff is improving and where can then evoluate to large enterprises;
- stimulates competition, helps in smooth functioning of large enterprises for providing various services or produce different subassemblies;
- manufactures products and provides services in terms of efficiency.

Sibiu county economic recovery is conditioned by SMEs access to finance. Reducing banks' interest to small customers, of the higher costs of credit and the requirements more stringent and creditworthiness of applicants, legislative instability, the sharp drop in demand for goods and services, high taxation, determined SMEs to reduce investment, postpone or abandon certain investment projects, renegotiate contracts with suppliers, to restructure / reduce activity and thus to reduce staff and salaries.

SMEs create jobs in a more efficient manner than state investment, with spending much less than budget and with a greater magnitude from social point of view because it involves family members and others in the locality.

Therefore, the authorities must take the necessary measures to support the sector: to increase allocations to programs for establishment and development for SMEs, simplify the procedures for their access to sources of funding by, to create a system of debt rescheduling (Ghenea, 2011). Development of small and medium enterprises is Romania's chance to restart the engines of economic growth.

Abstract

Education and training are crucial to the economic and social progress of a country, and the alignment of skills to the demands of the labor market plays and essential role in this progress towards a globalized and knowledge-based economy, where a competent labor force is required in order to be competitive from productivity, quality and innovation points of view. The present study aims mainly at achieving an analysis on the systemic reforms and the role the key actors (the students and the professors) play on the development of Higher Education so that it should integrate to the requirements of the European policy.

Keywords: higher education, systemic reform, students, teachers, educational offer, quality.

1. Introduction

Each member state of the European Union has a great responsibility towards its own system of education, training and the content of their educational programs. It supports the measures at national level and helps the member state to address common challenges through the concept known as "the open coordination method", providing a policy framework to discuss current issues and to exchange best practices.

Tertiary education, as stipulated by the EU Agenda for the modernization of Higher Education in member states, "plays a crucial role in the progress of the individual and of the society and in providing the high qualified human capital and of efficient citizens that Europe needs in order to create jobs, economic growth and prosperity." In such a context, the priorities set in *the National Strategy for Tertiary Education in Romania* will determine the main themes and objectives for the analysis, design, implementation and evaluation of relevant politics and initiatives, necessary for the development of Higher Education in Romania. These priorities will include - without limiting to them - new legislative and sector initiatives, identification of performance measures and estimation of program interventions. Consequently, the main areas of action will be: the promotion of a larger participation to tertiary education, especially for the under-represented groups; the improvement of tertiary education quality and relevance; the development of commitments towards economy, especially towards the relationship with labor market and the innovation/entrepreneurship; the consolidation of governing, monitoring and evaluation (the National Strategy for Tertiary Education 2015-2020).

In the past 25 years, the process of internalization of Higher Education has gained a central place on the European public agenda of national governments, of Higher Education institutions, of the actors in the Higher Education system and of the accreditation agencies in the enlargement context of globalization and economic and political integration (Hans de Wit, 2011). Thus, internalization has

acquired a significant role in the formation and consolidation of intercultural, linguistic and international abilities which should facilitate the graduates' interaction in a global environment, increasing their employment opportunities and implicitly, their life quality. Also, the public agenda of the European Union supports the intensification of the internalization process of Higher Education, encouraging quality assurance, mobility growth, promotion of common diplomas and facilitation in the recognition of qualifications and study periods, mainly in the context of universities' modernization for a competitive Europe in a global and knowledge-based economy (Egron-Pollak & Hudson, 2014).

The focus of efforts, so that Romania will have joined, by 2030, the states with advanced economies in Europe, represents the main objective of the vision to develop tertiary education in Romania. According to this vision, in 2020, the competitive tertiary education will be the engine of economic growth, will contribute to an increase of productivity and will promote social cohesion, thereby laying the foundations of a knowledge-based economy (Dragomirescu-Găină & Weber, 2013). Higher Education will train specialists who will be able to develop a competitive society in a global economy. Higher Education institutions will manage to catalyze the creativity and innovation throughout the society in Romania and, especially, to support the economy in developing products and services.

Tertiary education is the level of education offered by the public entities of Higher Education. Low levels of graduation rate in tertiary education can prevent competitiveness and undermine the EU potential to generate "smart growth". It is likely that an increasingly higher number of jobs in the future requires superior studies and, consequently, the EU member states will face the following main challenges: widening the access to Higher Education by increasing participation (especially among the disadvantaged groups); reducing the number of students who leave tertiary education without any qualifications; reducing the period necessary for people to complete their studies; the increase in quality of the Higher Education system by introducing more pertinent university programs for the professional environment.

As noticed, in the 2020 European Strategy, the main objective regarding the graduation rate in tertiary education - that is, the share of the population holding an academic diploma or some similar qualifications - stipulates that at least 40% of the young people between 30 and 40 years old should be graduates of the tertiary education system or of any other equivalent forms of education, by 2020. The graduation rate in tertiary education in the EU increased constantly from 22.6% in 2002 (the start year of the EU-28 series), constant yearly increases being registered. In 2014, almost 37.9% of the population between the ages of 30 and 40 had completed tertiary education, which means a rate with 0.8 percentage points higher than the one in 2013. If the proportion of young people between 30 and 40 years old with academic studies continues to grow apace with the progress made in the past years, then the main objective of 40% of the 2020 European Strategy is likely to be achieved by that date.

The role of education in achieving some social and economic goals is not obvious for the majority of the population. Equity and economic growth represent reacheable objectives with the help of the educational system, especially its university component. In one of his works, (Halász, 2015), he stated that reaching an optimal percentage between a meritocratic education system and one in which social aspects prevail is an extremely difficult process. Higher education, as a whole, represents an overall institutional system which provides high level qualifications as a result of some professional and academic training. This ensemble is made up of providers of education (academic institutions), actors (students, teaching personnel, parents, employers, etc), regulations, rules and social practices. Higher Education is organized as a market, in the very broad meaning of the term, where the suppliers of educational services provide study programs to students and potential beneficiaries at various levels (bachelor, master, doctorate). The system works mostly on the principle of supply and demand. The State is an important social actor that intervenes in the transactions between actors to remedy the disfunctions caused by the market imperfection. The intervention of the State is carried out through educational policies in Higher Education.

The transition from achieving the policies based on intuitive principles in Higher Education to their substantiation on concrete data is imperative for sustainable development of Higher Education (Burja & Burja, 2013). The specifics of the evaluation and accreditation systems in the country and abroad require this transition to ensure performance in Higher Education. Irrespective of context or area, the decisions and actions of individuals are triggered by a series of various factors, from intuition or common sense to diverse personal or group interests, as stated by some in their studies (Cooper, Levin & Campbell, 2009). Although there are numerous studies and researches of high scientific rigor that have a particular practical application in Higher Education, these have to be encouraged, and the decision-making actors must be continuously involved in all the stages of these demarches of research from description, implementation and to the analysis of results.

2. Aspects of the transition from repairing reforms to the systemic reform

The educational reform programs drafted since 1990 in Romania had a strong repairing, remediation character of some serious malfunctions. Meanwhile, in the Romanian society there had been important changes at social, cultural and technological levels. At the same time, the Romanian society has been more integrated into the processes of globalization and European integration, supporting their consequences more intensely. Education has to take into account the domestic and international changes and remodel according to them.

The reforms made so far have been designed independently for each educational subsystem. Considered separately, the sector programs of education reform made impressive progress as compared to the previous period. The analysis of these programs as a whole highlights a series of disarticulations between componentsv (Curaj et al., 2015). This is why, a transition to systemic transformation was necessary, a transition where each component of the education system be reconsidered in relation to the other components.

In this perspective, the systemic reform of education in Romania was to be achieved through the following ***actions:***

- The inclusion of lifelong learning (including its particular forms: adult or recurrent education, continuous training/formation, compensatory or "second chance" education, etc) in all global or sector development programs, both at national and regional and local levels and the focus on the development of a knowledge-based Romanian society;
- The analysis of formation/training needs, the elimination of outdated specializations, the development of professions which are deficient in the number of workers and which are culturally and economic necessary, the development of new qualifications in relation to the current and perspective requirements of the labor force market. The elaboration of a national policy of initial and continuous training, correlated with the other sector strategies and with the dynamics of the labor force market at national and international European levels will be possible by/via:
  - ✓ A better correlation of the State Higher Education with the labor force market;
  - ✓ The re-analysis of State education structure in order to optimize it;
  - ✓ A better correlation between academic specializations and the nomenclature of jobs;
  - ✓ Monitoring the way of graduates insertion into the labor market;
  - ✓ Optimizing the practice activities in the educational process; developing the vocational side in the training of specialists;
  - ✓ Broadening the content of academic qualifications so as to increase the graduates' chances onto the labor market and to lead to the release of funds and resources which contribute to the development of the quality of education for the remaining specializations.
- Clear formulation of educational policy option for mass Higher Education:
  - ✓ Defining the concept of mass Higher Education with its various forms;
  - ✓ Redefining the networking of Higher Education in relation to the mass character;
  - ✓ Redesigning the admission system;
  - ✓ Including the students into an academic route in relation with their motivations, abilities and performances;

- ✓ Modifications in the teaching methodology and in the learning facility contexts;
- ✓ Making flexible the routes of study in relation with the students interests and performances;
- ✓ Introducing the selection system throughout the studies.
  - ➢ Adopting a new *Law of social service* which forces the graduates of specific study programs to achieve a trainee-ship with duration of up to one year, in the rural and deprived areas, before receiving a diploma. The provisions of such law should also contain incentives.
  - ➢ Developing an anticipatory and creative character of Higher Education by promoting new qualifications and jobs on the labor market in relation with technical and scientific innovations. University education should come out of its relative isolation and integrate more in the dynamics of society and communities.
  - ➢ Developing university autonomy.
  - ➢ Promoting the variety of options for implementing some fundamental decisions in solving certain punctual situations. .
  - ➢ Supporting the objective process of universities concentration; the formation of large universities (by unifying the existing ones) in order to ensure the increase of efficiency and competitive capacity.
  - ➢ Integrating accredited universities, state and private, into a single national system of higher education, with two components having distinct specifications, but which cooperate to accomplish the same national targets; regulating the competition between them by offering complementary financing; integrating the two components into a unique national policy, appropriate for both the entities in the public and private law.
  - ➢ Supporting the formation of some great universities by urgently clarifying the situation of their real estate assets, in the spirit of the *Education* Law; by adopting legislation to encourage the donations made to educational institutions, by means of tax incentives, thus granting the universities a genuine independence towards these donations; by unequivocal definition of tax breaks and subsidies.
  - ➢ Supporting academic research by revitalizing master and doctoral programs; PhD programs will be redefined as research teams organized on themes, with compulsory meetings (weekly, monthly), with a file of periodic reports; research centers will focus on a limited numbers of themes where the university is competitive at international level; a significant importance will be given to the scientific councils at university level, with a limited number of members, which shall define an institutional policy and will dispose of means to implement it; scientific councils will make decisions based on the evaluations coming from colleagues and experts. Doctoral schools will be set up and centers of scientific excellence will be selected.

3. The Role of Higher Education in the Modern State

In the last two centuries, one of the fundamental missions of universities was to form elite capable to govern the State. The State accepted to fund universities because universities were in the government service, meeting with the highly qualified personnel needs for its public services. In addition, the cost of Higher Education was relatively low; it was no burden for the public budget (Măcriș & Ciurea, 2013).

The development of Higher Education in European countries during the last three-four decades has modified the main role of universities, changing them into institutions oriented towards meeting the needs of the productive system of the society, in general. The State ceased to be the main beneficiary, unique and direct, of the Higher Education system.

Private entities shall benefit, in turn, from the services and product of Higher Education. Here are some of the arguments in favor of this statement:

- ✓ *General academic training reduces the period of formation or recycling when new technologies are introduced;*

- ✓ *High productivity of educated people (especially of academic diplomats) is transferred to the other employees and has an important effect on the business as a whole;*
- ✓ *A significant part of external benefits produced by Higher Education graduates is absorbed not only by the society, in general (which actually justifies public funding), but by enterprises/businesses, too;*
- ✓ *Businesses are the first beneficiaries that take advantage directly from the scientific and technical progress achieved, at a large extent, by universities.*

There are individual benefits of university graduates, apart from the ones raised from membership to a state or public entity. One of the most important benefits is the high value of an academic diploma on labor market. In the OECD countries, the rate of participation on labor market of university graduates is with approximately 15 percent above average. At the same time, the rate of unemployment is of 4.7% for university graduates as compared to the average of 8.5%, and the salaries of those with an academic diploma are net superior to those with a lower qualification (European Commission, 2013).

The benefits granted by the labor market represent only a part of the benefits obtained by the persons with an academic diploma. Other economic and social benefits are more difficult to quantify, but everyone agrees that diplomats are not only more easily absorbed by the labor market and do earn more money, but they also have a more elevated social status, they show greater efficacy in terms of consumption, they benefit from better health and they adapt more easily to technological changes. They also have a series of cultural advantages.

4. The Radiography of Higher Education in Romania after 1990 and up to Present

In recent decades, the demand for Higher Education has steadily increased up to a point when it started to decrease considerably. In Romania, the number of students from accredited universities increased from 183.000 in 1990 to 281.386 in 2006, the historical peak being reached in 2007, when there were 907.353 students enrolled. This growth is the main factor of the financial crisis increasingly emphasized which has reached the European Higher Education since 1970.

The increase of the number of students was followed by important structural changes. There were numerous antennae of traditional universities dedicated, especially, to vocational education. The development of this type of education was done with higher costs, generally, than in traditional education. And the lack of a clearer difference between the institutions of Higher Education from a point of view of objectives and structure was also added. The Humboldtian model of university was promoted in numerous European countries as a unique system of knowledge transmission and highly competent specialists' training.

A clear trend of the Romanian Higher Education shown immediately after 1989 is that of generating a market of tertiary level educational services which try to answer, via specific and competitive offers, the continuous increasing demand for training manifested among high school graduates. Thus, the emergence of a private Higher Education, and its development in 1990, further completes the educational offer of the system. According to Ordinance No. 54 of the Ministry of National Education, starting with the university year 1998/99, they have created a legal basis regarding the access to public Higher Education with payment of a tuition fee, over the limit of places financed from the budget, thus extending the chance to meet with the continuous demand for education of high school graduates.

Another trend of the Romanian Higher Education is the diversification of the educational offer. ***This is achieved by:***

- ✓ *Structure on fields of study and specializations/majors;*
- ✓ *Diversification of the forms of organization types of units and forms of study;*

✓ *Candidates access to more specializations; in public Higher Education, the candidate admitted to more specializations on places without tax is supported by the state budget to a single institution of Higher Education;*

✓ *Students' mobility between public and private education institutions based on the transferable credits system.*

In the early 90's, the structure on the main fields of study registered important changes, by significantly restricting the option for a technical domain and the extension of the economic and academic education.
A look on the vertical, on the dynamics of the groups of students' distribution on the fields of study in the last decade, indicates (subject to some statistical reports which might not be fully accurate) the following:

- After spectacular reconfigurations occasioned by the "post-revolutionary" changes, a certain structural balance is manifested, which makes the university to react cautiously to the fluctuation on the labor market. The statement also covers private education, even if it seems to be a little more mobile. We may interpret this relative stability either in terms of inflexibility (as an extension of an immutable university tradition) or as a sign of normality of the academic evolution (university cannot and does not have to keep up the pace with the expectations, sometimes anarchic, of a less mature labor market).

- The two systems, the public and the private, seemed to have evolved in the mirror, developing certain fields of study in duality. Thus, one can compare the shares of the legal and technical-agricultural fields of the two types of education.

- In the recent years, there has been a slight increase of the economic and university fields, both in the public and private education, maintaining the percentage distribution from the mid-90s.

The recent diversification processes should have led to a decrease in the costs of Higher Education. However, the non-academic sector of Higher Education, at first oriented towards the short duration programs, has evolved through a kind of an academic switch towards increasingly longer programs, requiring, at the same time, a rise in subsidies. The negative effect of this process is the high cost and the inefficiency, as a whole, of the Higher Education system in many European countries. Thus, one can observe a permanent increase, at a large scale, of the number of students in Romania, but the analysis of the situation would not be complete if we did not report the number of students and the evolution of this number to the dimension of the academic personnel in the system and its dynamics.

It can be noticed that, according to the data in table 1, from a ratio of 14 students to a professor in 1990, a report comparable with the values from *real and prestigious* universities (11at Cambridge, 13 at Oxford in 2005-2006), the ratio rose to 23 students in 2005-2006, to 28 students in 2008 and later the ratio dropped to 15 students in 2014. This situation shows a drastic diminution of quality, which would have been bearable, but the situation is much worse than this if we considered the indicator of "net unit cost per student", which also clearly expresses a decrease in quality.

The indicator thus registers, for the fourth consecutive year, a declining value, reaching at the same time the lowest level in the last decade. The value of the indicator is determined both by the decrease (in absolute values) of the number of registration in Higher Education, as well as the increase of the number of professors, in the context of advertising new vacancies in the system.

From the perspective of ensuring quality in Higher Education, the evolution of the indicator can be considered as positive. Thus, the allocation of human resources in universities according to the needs of direct beneficiaries (the students) can be considered as constantly adequate. The evolution of the indicator value can be interpreted in correlation with the fluctuations registered within the groups of students and groups of professors. We notice that, historically, the number of registrations in universities fluctuated greatly over the last 15 years, at least in absolute values. Simultaneously, the

number of professors employed in the system fluctuated less significantly, the evolution of the number of professors being different, in terms of direction, from the evolution of the number of registered students (Vlăsceanu, et al., 2011).

As such, it cannot be stated that there would be a direct relationship or flexibility of the universities in terms of human resources management in correlation with the number of registrations. In this interpretation, the value of the indicator can signal a short-term problem of the academic system, that is the sub-utilization of the human resources employed. If we analyze the indicators in an integrated manner (including students, master students and doctorate holders), we can consider that reducing the participation to Higher Education at the undergraduate level will have as an effect, among others, a sub-utilization increasingly higher of the teaching personnel with certain teaching positions, existing in universities.

Table 1: Evolution regarding: the number of students, teachers and the students' share to a teacher

Study years	Number of students	Number of professors	Share of students per teacher (Students/1 teacher)
1990	192.810	13.927	14
1991	215.226	17.315	12
1992	235.669	18.123	13
1993	250.087	19.130	13
1994	255.162	20.452	12
1995	336.141	22.611	15
1996	354.488	23.477	15
1997	360.590	24.427	15
1998	407.720	26.013	14
1999	452.621	26.977	17
2000	533.152	27.959	19
2001	582.221	28.674	20
2002	596.297	29.619	20
2003	620.785	30.137	21
2004	650.335	30.857	21
2005	716.434	31.543	23
2006	785.506	30.583	26
2007	907.353	31.964	28
2008	891.098	31.973	28
2009	775.319	31.103	25
2010	673.001	29.746	23
2011	539.852	28.365	19
2012	464.592	27.555	17
2013	433.234	28.211	15
2014	411.229	27.772	15

Source: INSSE data – TEMPO-online processed by the author

The network of Higher Education during 2004-2005 included 117 institutions and 742 faculties where 650.3 thousands students attended the courses. In this context we distinguish:

• public Higher Education - financed from the state budget, supplementing the access of places with fees to be paid: 55 institutions with 510 faculties, where 495.0 thousands students study.

• private Higher Education: structured by 62 institutions with 232 faculties, where 155.3 thousand students study there.

In 2014, in Romania, there operated 56 public universities (state ones) and 47 private universities (private) according to the data published by the National Institute of Statistics, which were accredited or authorized to function temporarily. We take into consideration those organizations which manage programs at academic level, are accredited at institutional level according to the law and which have implicitly obtained the right to use the title of *university or any other similar name*, and where there operated 590 faculties (out of which 450 within universities funded from the state budget), 433,234 students were registered there (out of whom 353,988 were registered in the faculties from state/public universities). It should be mentioned here that the available data do not permit the identification of the exact number of unique persons registered in the universities in Romania, be them public or private. This is because a person registered in more universities can be counted several times and the Unique Registry was not operational at the date of this study. It should be noted the continuing trend of quantitative contracting of the Higher Education system in Romania. Thus, the mass trend prevalent in 1990-200 was reversed starting with the academic year 2009/2010, under the combined impact of numerical decrease of those born after 1990, of the reduction of the number of study years at the undergraduate level due to the implementation of the Bologna system starting with 2005 (with statistics effects visible in 2008 and 2009) and of the decrease of baccalaureate graduates (an effect combined with school dropout in secondary education and with the increase in exigency of the baccalaureate exam starting with 2011). It is obvious that there are more potential sources for the constant and drastic decrease of the number of registrations in the universities in Romania. The extremely low transition rate from undergraduate study programs to those of master visibly affects the rates of enrollment by age of young people at this level of education. Apparently, there is no significant statistical relationship between the absolute values of the population of secondary school graduates of the national education system and the number of registrations in the 1st year in public universities. These descriptive findings should represent the basis of some detailed studies which should correctly identify the sources of the registrations decline in the universities in Romania and which should also propose informed public policies to correct these trends.

Gradually, the negative demographic increase and the unfavorable financial caused that a larger number of potential students not to attend university courses. The decrease is extremely high, reaching only a number of 411.2 thousands students in 2014, with 45.32 % less students than in 2007. This is the largest decrease of any contingent of students within European Area of Higher Education.

The number of high school graduates who didn't manage to pass the Baccalaureate exam was continuously increasing. Thus, if in 2004, 84.54% of the students succeeded in passing the maturity exam; in 2015 only 67.9% gained the same performance. In 2012 only 43.88% managed to get the Baccalaureate diploma, while in 2013 the percentage rose a little over 45% (46.23%). These results were immediately seen, the number of candidates acceding to Higher Education being much lower.

Another element which can affect these values is represented by the number of Romanian citizens registered to universities from other Member States of the European Union. According to the data made available to the public, reported by Eurostat, approximately 37,000 Romanian citizens were registered to programs of study at bachelor or master levels at a university from another member state of the European Union. This aspect is shown in the following table:

Table 2: Romanian students registered at universities from EU member states

Years	2008	2009	2010	2011	2012
Number of Romanian citizens registered at a university in another EU country	21.267	25.077	28.578	29.159	37.228

Source: Eurostat, online database, 2016

After 1989, as the attitude of disregard towards the teachers' guild kept maintaining, an important part of the best professors left the system either by emigration or by migration to more attractive fields of activity, including to the private sector in formation. Consequently, the capacity of the academic

system was drastically reduced. Although, considering this kind of increase in the number of students (as presented in the table above), starting from a major shortage of professors, there should have appeared an increase in the number of teachers, too. Under these circumstances, the university system, logically, should have been reduced (Pricopie, et. al., 2011). Thus, we concluded that the decline of the number of Higher Education institutions should not deceive us because the number of faculties and, especially of students, continued to grow. Nevertheless, the share of population with academic studies in Romania remains one of the lowest in Europe.

Therefore, an explanation for the increase of costs also lies in the universities concern regarding the quantity and quality of the services provided: universities are concerned with the expansion and improvement of the services offered to students and to the community, in general. Finally, the private "production" system in Higher Education contributed, in its turn, to costs growth. This system has been marked to a less extent by the technology changes. In the competitive sectors of the economy, the technological changes are gradually introduced in the production system, thus having as a result a natural increase of productivity (Măcriș & Man, 2014). On the contrary, the production system of Higher Education still uses, to impressive extent, the same core technology used a century ago (courses, seminars, etc). .

Consequently, summarizing, the financial crisis of Higher Education can be described as follows:

- ✓ Higher Education turned, from an elite higher education, into a mass education;
- ✓ The costs of Higher Education have increased;
- ✓ The State ceased to be the unique beneficiary of product and services of Higher Education;
- ✓ The economic entities and their individuals benefit directly or indirectly from these services and the State is no longer interested in supporting the costs of Higher Education solely.

In order to obtain optimal educational results by managing the existing resources and in order for education to meet with the social-economic needs, it is required to take into consideration the following criteria: the increase of competition in selecting the candidates from State Higher Education; meeting with the commitments under the 2020 European Strategy framework, regarding the tertiary education indicator; using the results of the studies on graduates insertion onto the labor market; ensuring a gradual transition which should not endanger the fragile equilibrium of the Higher Education system.

However, after finalizing the project *Politics based on records and the impact on labor market force,* implemented under the Sector Operational Program Human Resources Development, it is necessary that the Single Registry can be operated after the issuance, by the Ministry of National Education and Scientific Research, of a piece of legislation which should request all Higher Education institutions to upload their groups of students to RMUR which, in addition to the facilities granted to universities in receiving the information regarding the previous educational route of the students, will allow the analysis of the correlation between the educational offer and the demands of the labor market, thus turning into an important tool in evaluating and optimizing the activity in Higher Education.

5. Conclusion

The numerous changes that have occurred in education, which has been in a permanent transformation, the latest legal regulations in education, as well as the restructuring process of the National System of Education, have led to a reorganization of the network of Higher Education institutions in Romania. Therefore, after a thorough examination of current realities in tertiary education system in Romania, resulted from consulting the specialized literature, have made us identify the main issues which represent barriers in achieving some strategic objectives and these would be the following:

- ✓ After registering a huge number of students at the beginning of the 90s, this number decreased in 2007-2008, thus forcing the universities to reassess their recruitment methods and their study programs;

✓The funding mechanisms are not sufficiently flexible to offer incentives for modernization, efficiency, innovation or equity;

✓The quality on various levels and forms of tertiary education is uneven, especially in the private tertiary education and the non-university one;

✓The correlation with the demands of the labor market has to be consolidated - especially when in terms of transversal skills;

✓ The participation to Higher Education of the young from the rural environment, of the poor population and of the minorities is inferior to that of the students coming from the city, who generally have higher income;

✓The international mobility and the experience exchanges for students and teaching staff are far beyond the European average.

Given the mentioned aspects, it is necessary to substantiate some courses of action which should be taken into consideration by the national strategy for the development of participation, quality and efficiency in tertiary education, based on the following considerations: Romania is engaged in harnessing the opportunities granted by the European Union and the Member States and it uses the basic documents and the political directives of the EU in developing these actions; Romania uses the best practices to build a relevant, efficient and effective tertiary education on short, medium and long-term; Romania is engaged in developing tertiary education as an important tool in the general strategy of social-economic development, thus supporting all other development plans and initiatives of the State, especially, the National Reform Program, the National Strategy for Competitiveness 2015-2020 and the Innovation-Research-Development Strategy.

Another finding, highlighted both by the developments in the last years and the international comparisons, refers to the aggravation of the chronic sub-funding of the Higher Education system in Romania. Although in 2014 the funding from the state budget of Higher Education improved in nominal terms, the growth was lower than the inflation and totally insufficient in relation to the financial needs/obligations of the universities. However, even worse than that is the fact that the income earned by the universities from extra-budgetary sources were limited by the decrease of the number of fee-paying students, which made the institutions of Higher Education depend, to a large extent, by the allocations from the State budget. The uncertainties and the insufficient volume of the funding, on the whole, affect negatively the quality of Higher Education and the competitiveness of universities in Romania on medium and long-term, undermining the chances of sustainable development of the Romanian society in the 21st century. This is why, it is important to strengthen and improve the mechanisms for a correct and efficient exploitation of existing resources so that it should be accompanied by the existence, at national level, of a coherent strategy and of a set of priorities for the long-term development of the Higher Education system in Romania. Despite the inherent limitations of any study, the issues approached along the study represent only a part of the researched field, but of vital importance for the future of the Romanian Higher Education to achieve the strategic objectives of the European Union.

Abstract

This paper examines the impact of vehicles on sustainable development in Romania. Public data are used to assess the trajectory of vehicle categories and types of fuel. It also contains the evolution of electric vehicles that are perceived as key technology in the automotive industry that contributes to sustainable development by reducing emissions of greenhouse gas emissions, less pollution nationally and internationally and new employment opportunities with positive social impact. The automotive industry is one of the major polluters among national sectors. This pollution is analysed in terms of greenhouse gas emissions and climate change. Sustainable development involves balance in the use of resources so that future generations have the same resources as today. The climate change is a concern now because there have been a number of changes globally. Therefore, the paper analyses the impact of the automotive industry, the evolution of the number of vehicles and CO_2 emissions on sustainable development. In this analysis we used statistical data, public data and experimental data (through visits at the automotive companies). In the end, the analysis conclusions are presented.

Keywords: Sustainable development, automotive, greenhouse gas emissions, environmental pollution.

Introduction

The relationship between business and sustainable development (SD) has become one of the central debates in countries that have already experienced industrialization and those that are currently under development (). It is obvious that in some respects business models may be inadequate and insufficient to meet the challenge of sustainability (Babut et al., 2011). Therefore, the conferences and debates that took place over time have established directions and indicators. When we speak of SD, the three responsibilities that need to be analysed are: environment, social and economic. Developing a balance between these responsibilities contributes to sustainable development (Fuller and Morgan, 2010; Dammenhain and Ulmer, 2012). The present paper, mainly addresses environmental responsibility and the impact vehicles have on the environment. This impact is analysed in terms of the number of vehicles and gas emissions. These emissions contribute to global climate change. Addressing climate change from the SD perspective becomes imminent (Ivascu and Cioca, 2015).

Climate change is a current problem, including the following phenomena: changing seasons, rainfall patterns are changing, glaciers and snow melt, and the average global sea level rise annually. Individually assessing these phenomena it can be said that the climate change represents the increase of the average temperature at Earth's surface. A scientific consensus supports that climate change is primarily due to human use of fossil fuels, which releases carbon dioxide and other greenhouse gases (GHG) in the atmosphere. Greenhouse gases have a number of negative effects on ecosystems, including the sea level rise, severe weather events, droughts and landscapes more susceptible to fires (Skippon et al., 2012). These effects are felt globally.

Climate change

Globally, the annual average temperature of Earth increased by 1.4 ° F over the past century and is expected to rise to 11.5 ° F, if we maintain the current level of consumption and intensity of activities in various fields. These are not high values, but the average temperature during the last ice age must be considered which was about 4 ° F lower than it is today.

The Intergovernmental Panel on Climate Change (IPCC), released in the last decade a number of important reports which highlight the complexities that climate change causes in the world as a whole and in different regions and locations of the world. Under the "Report of Global Assessment of Climate Change (AR5), number 5" developed by the IPCC (Intergovernmental Panel on Climate Change) it is presented in a complex way the last results and scientific discussion about the causes of climate change and its impact on short, medium and long-term. In the report there were analysed also various options for adaptation to climate change and emission reduction, including specific interdependencies specific to the sustainable development of society, given the socio-economic and scientific issues relevant on long-term (IPCC, 2016).

Earth's atmosphere is made up of water vapour (H_2O), carbon dioxide (CO_2), ozone (O_3), methane (CH_4), nitrous oxide (N_2O) and sulphur hexafluoride (SF_6), which are part of gas greenhouse effect category. The most common five greenhouse gases (IPCC, 2016) that occur naturally are:

 Water vapour (H_2O): Amount of water in the atmosphere increases at the same time with the temperature of the surface. People do not directly influence the amount of water vapours in the atmosphere, rising temperatures due to the activities of humans causes increase in the concentration of water vapours.

 Carbon dioxide (CO_2) is increasing in the atmosphere due to fossil fuel burning processes, rotting processes, animal life processes, and the process of plant development.

 Methane (CH_4) retains heat at an intense pace, making it a very powerful greenhouse gas. It occurs where organic matter rots in a space where there is no oxygen.

 Ozone (O_3): This is naturally in the stratosphere and plays an important role in protecting the Earth from ultraviolet rays. It represents around 2% of GHGs.

 The hydrocarbon group are chemicals produced by people who have a significant share in the greenhouse gas category.

Of these GHGs, the automotive sector generates a large amount of CO_2 that contributes to climate change and thus have an effect on the environment.

International steps

COP21 (Conference of the parties) is the 21th United Nations conference on climate change, which took place from 30 November to 11 December 2015 in Paris, is the most current action in this direction. In this summit, 195 countries have adopted the first universal agreement in this process of global warming (Sustainable Innovation Forum, 2016). The conclusions of this meeting are:

 Increasing global temperature to 2 ° C above pre-industrial levels and sustained efforts to limit the increase to 1.5 ° C;

 In terms of reducing "global emissions limit" this must be reached "as soon as possible" of all countries;

 The agreement stresses that developed countries can support those affected by major weather changes. Technology transfer is an effective way to combat the consequences of global warming;

 From a financial perspective, the agreement establishes the collective target of allocating 100 billion dollars since 2020 for loans and donations to allow the support of those worst affected (in terms of drought, floods, rising sea levels, et al.) to adapt to climate change and / or reduce emissions of greenhouse gases. Some developing countries could on a "voluntarily" base provide support to the poorest countries;

 In promoting transparency, this approach introduces a mechanism for monitoring the commitments every five years since 2025 (agreement becomes valid in 2020). A first meeting between the parties has been established in 2018 to assess progress towards achieving the objectives set;

 Carbon price has been another area of interest. The agreement underlines the desirability of a structured framework to encourage stakeholders to reduce their emissions.

So COP21 Paris 2015 kicked off a fundamental change in humanity, based on evolution. This summit is a reference for all countries that contribute to reducing GHG and thus to halt climate change globally. All these actions are undertaken in order to sustainable develop.

Climate change in Romania

The reduction of GHG in Romania has already started. Romania has halved emissions of greenhouse gases (GHG) in recent years, being actively involved in various activities which have contributed to the objective (European Environment, 2015). In our country, sulphur dioxide emissions fell by around 48% and NOx emissions are down almost 30%. Research points to certain signals produced in Romania, supporting this hypothesis of climate change (European Environment, 2015):
 Frequent appearance of non-specific weather events to climate in Romania;
 Climate aridity, registration of extremes temperature and heavy rain;
 Very intense and frequent rain which have a significant impact - 285 mm rain fallen in 30 hours in Bucharest in 2005;
 Increased duration of dry periods, especially during the summer;
Recording a catastrophic flood frequency of 6 / year;
 Increasing the maximum annual flow on the Danube approximately 1,200 m / s;
 Glacier Scărişoara is decreasing by 150 cm in the past 100 years;
 Black Sea level has risen every year;
 There is alternation between dry and rainy periods.

So climate change is felt in Romania, so the reduction of GHG is supported nationally by actions and steps. In Romania, the most polluting sector is energy, followed by transport and construction (NIS, 2016). The transport sector is one of the pollutants factors, thus this paper shows the impact of the automotive sector in terms of number of vehicles registered, the number of electric cars and CO_2 emissions (Cioca et al., 2015).

Automotive sector in Romania

Evolution of automotive sector in Romania is linked to influential factors related to the financial dynamics, the unemployment rate as a factor for weakening demand, reputation and experience of carmakers on the Romanian market, fees paid to register new and used vehicles, the concentration of population, the degree of openness of authorities towards worldwide existing competitors to help the industry, the availability of loans to finance durable goods, including cars and other factors. In late 2014, the situation of registered vehicles based on fuel types is presented in Table 1. Note that buses and minibuses sector recorded a smooth decrease in 2013-2014, due to lower passenger levels. Trucks category also recorded a decrease in the number of vehicles registered, a contribution to this decline is done by the financial institutions that no longer offer loans as easily as in previous years.

An increasing number of vehicles can be found in cars category, which registers more cars annually. The largest share is held by gasoline cars because registration fees and national taxes are lower. Instead, the companies buy diesel cars because of the high number of kilometres (Taticchi et al., 2014). For diesel cars, the highest consumption is recorded and therefore they have the highest rate of pollution (Kim et al., 2014; Seurin, 2013). There is a higher demand for electric cars in 2014 registering 30% more vehicles than in 2013.

Table 1: Number of Romanian registered vehicles (Source: INSSE)

Category	Fuel Type	2010	2011	2012	2013	2014
Buses and minibuses	Petrol	154	146	141	135	132
	Diesel	40647	40650	41778	42607	44052

	Natural gas	2	6	16	23	45
Total		636077	665990	642241	676607	712317

Evolution of the number of vehicles per category in the period 2010-2014 is presented in Figure 1 (a). It is noticed that cars category recorded the highest share in total registered vehicles and truck lowest number. Figure 1 (b) provides the evolution of the number of vehicles, totalling categories. In 2014 there were registered 14% more vehicles, the highest rate is recorded in the cars category. It can be concluded that the category cars emits a high level of GHG.

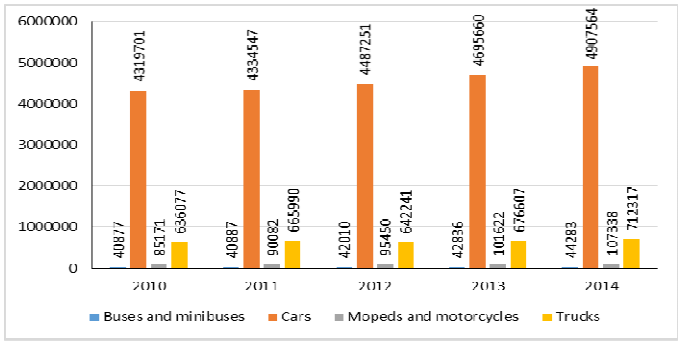

Fig 1(a): Evolution of vehicles by category registered in the period 2010-2014 in Romania (Source : INSSE)

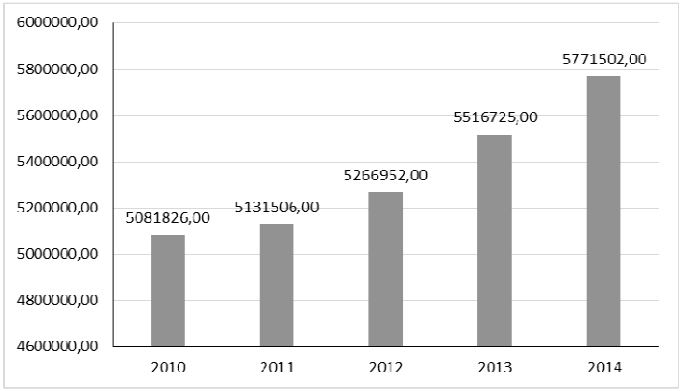

Fig 1(b): Evolution of the total number of vehicles registered in the period 2010-2014 in Romania (Source : INSSE)

According to INSSE, 2016, the automotive sector has consumed in 2013, 5.7 million tons of fuel, and in 2014 the volume increased. To quantify CO_2 emissions there were used mainly standard IPCC conversion factors for final energy consumptions analysed. These factors are shown in Table 2. Using the conversion factors afferent for gasoline and diesel, Figure 2 shows the CO_2 emissions recorded in these two sectors.

Table 2: The Conversion factors (Source: IPPC)

Fuel	Conversion factors used tons CO_2	Source
Petrol	0,249	Standard Factor IPCC
Diesel	0,267	Standard Factor IPCC
Electricity	0,701	Standard Factor IPCC
Liquefied Petroleum Gas	0,231	Standard Factor IPCC
Natural gas	0,202	Standard Factor IPCC

Since most cars use petrol and diesel as fuel, Figure 2 shows the CO_2 emissions in these two categories. Total CO_2 emissions in 2014 are 1.54875 million tons CO_2 / year, representing a high level. By motivating the population, residents could use public transport or to purchase electric cars. The cost of an electric car is high compared to the national level.

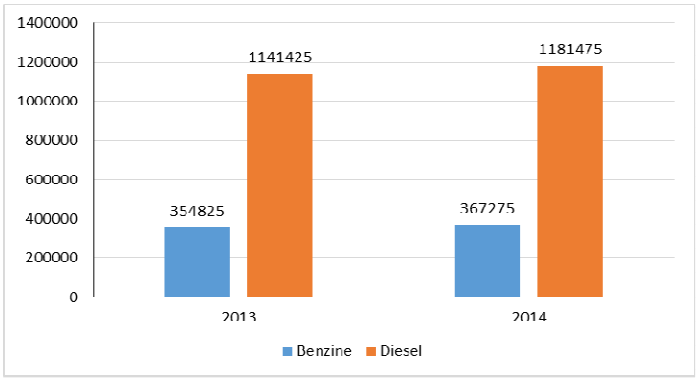

Fig. 2: CO_2 emissions for the petrol and diesel cars (tons / year)

In Figure 3 presents the evolution electric cars that were registered in Romania, as only this recorded a significant number. Category buses and minibuses and truck have a very small number of electric units, zero even in the earlier period. In the cars category, it is observed that their number represents 0.05% of the total number of cars registered, and the trend of the number of vehicles registered is an upward one. In 2014 there were registered 3.5 times more electric cars than in 2008.

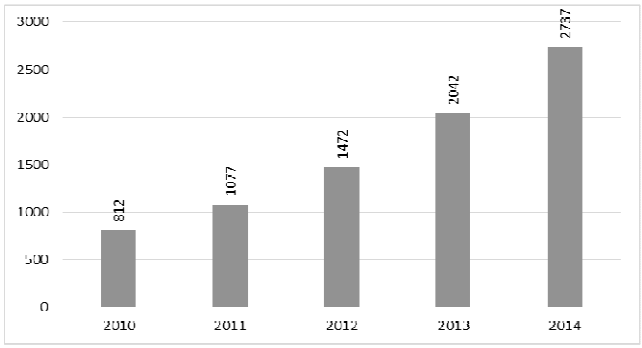

Fig. 3: Evolution of the number of electric cars in Romania (Source : INSSE)

The number of electric charging stations in Romania is about 45 stations, these being found mainly in larger cities. Therefore, users of these electric cars must adjust their traffic route depending on the positioning of the charging station. Map loading station is shown in Figure 4.

Fig. 4: Map of charging stations in Romania (Website, Electric car)

Technological evolution has contributed to the development of these electric vehicles so they lead to a variety of challenges and opportunities for national and international economic development (Gunther et al., 2014). While the electric vehicle market is still at an early stage of development, companies are prepared in addressing the opportunities and communities around the world (Ilgin and Gupta, 2010).

The potential benefits that these electric vehicles have on sustainable development are:

 Creating new jobs: although the oil industry would lose jobs, jobs will be created in industries closely related to auto manufacturing: advanced batteries, technology, research and development. Moreover, electric vehicles are cheaper to use than conventional ones. Drivers who will purchase electric vehicles will have more income available to spend in other sectors of the economy such as housing and services.
 Improving infrastructure leading to increased quality of life: reducing costs with pollution can contribute to improving infrastructure.
 Reducing oil imports: reducing the consumption of conventional fuels contribute to the reduction of their sale.
 Falling prices: reducing the cost of vehicles leads to lower prices on various sectors.
 Reducing GHG emissions: increase quality of life by reducing pollution.

Conclusions

The number of vehicles in Romania is increasing due to improving living conditions. Therefore, the level of GHG will be increasing and therefore new solutions should be provided to decrease GHG emissions, without compromising quality of life. Evolution of electric cars in Romania has an upward

trajectory, registering in recent years more and more such vehicles. Given this sector we can conclude the following:

• The number of vehicles registered is increasing leading to an increased degree of pollution;

• In Romania there are incorporated many used cars as a result of lower prices, so with higher levels of air pollution.

• CO_2 emission level is rising (see Figure 2);

• The number of charging stations is low and is concentrated in major cities in Romania (see Figure 4);

• The routes of the ones owning such electric cars need to be adapted depending on the positioning of the charging station;

• The autonomy of electric cars is not a strong pillar in this technology.

The infrastructure in Romania is at an acceptable level, but can be vastly improved (only 228 kilometres of highways and 21,500 km of national roads and local roads out of about 80 thousand kilometres in 2006). Public roads density is low (33.5 kilometres per 100 square kilometres in 2005 compared to the EU25 average 110.1 km per 100 square km in 2003) lead to increase distance and travel time, the excessive fuel consumption, with adverse environmental effects, and a large number of accidents (753 deaths per 1 million registered cars in circulation), well above the EU average who register 189 cases (INSSE, 2016).

Abstract

There are a number of social security schemes and institutions in Malaysia but not all has the ability to address the long term financial commitments and provides the security during the old age. High in inflation rates, global economic growth and changes in employment and social structure have contributed in raising serious concerns on the efficiency of the current social safety net especially when the number of older people has increased due to the increase in life expectancy. An effective social safety net should be able to protect the welfare of a person at their old age and the existing social safety net in Malaysia is not sufficient. Hence, this paper examines the current social safety net in Malaysia for the older people and analyses the efficiency of protection provided. This paper further discusses the social safety net provided in other jurisdictions specifically in Japan and Singapore. In fact, this paper used the qualitative legal research methodology specifically a comparative and analytical research approach on the social safety net for older people in Malaysia by reference to the social safety nets as developed in these jurisdictions. The objective of this paper is whether to recommend an additional measure to be added to strengthen the current social safety net to ensure that welfare of Malaysians is well protected during their old age.

Key words: safety net; old age; social security

Introduction

According to a new World Bank Report, Asia Pacific region is faster in aging than other parts of the world and this could lead to a decline in the size of workforce in the nation and increase in spending on pensions and health care in coming decades. The older population grows by 22 percent in every five years in East Asia and Malaysia is one of the countries.[i] The higher the older population is in a country, the higher in demand of public spending. Though it is normal for rich countries to spend more on public services, the number of older people Malaysia will have in the next five to ten years is alarming and there is an urgent need for the country to review the efficiency of existing social safety nets for older people.

The pace of ageing in Asia Pacific Region varies; some countries have older population comprising as much as 14% of the total population like in Japan, Korea and Singapore whereas there are some other countries with an average of 4% of the total population like in Myanmar, Philippines and Laos. Malaysia is expected to be in the former category of 14% of ageing population by the year 2020 and thus social safety net for older people in Japan being with the highest number of older people and Singapore being the neighbouring country with the similar system of law will be examined in order to suggest the best practice to be introduced in Malaysia. Most of the older people in Malaysia are left in rural areas as their children have moved to urban areas in search of better paid jobs and hence they depend on their own instead of their family and state support. Though it is expected that the state will play a better role in supporting the older people, how the state meets that expectation is a key social and political challenge in the coming year. Hence it is the best for older people to have their own social safety net without depending much on their children and the Government.

However, the existing social safety net in Malaysia is not sufficient to cover the people at their old age and thus it is imperative to identify the best alternative option to be introduced by examining the practice in other countries.

1. Social Security for Older People in Malaysia

Social Security System is a system which protects and supports the people by providing necessary assistance during the time of poverty, unemployment, illness, injury, aging and etc. There are many social security schemes in Malaysia providing the foundation for universal social protection comprising of different social protections. Among them, public pension system for civil servants and Employee Provident Fund (EPF) for those is private sector provide income security during the retirement. In fact, Malaysia Government gives RM300 per month as financial assistance to those above 60 years old and do not have family and fixed income.[ii] However, these measures are not sufficient to shield the rapid growth of older persons in the country.

Nearly half of government's spending has been towards the welfare of elderly people and thus the increase in number of elderly people in the country indeed pose the challenges to the Government in spending public finances. It is vital that every citizen in their old age has access to healthcare, and should not pressure on the public health system of the Government. Hence it is important that those who can afford should rely on private health insurance in order for the Government to be able to provide quality assistance to those who cannot afford it.

There are a number of social security schemes and institutions in Malaysia but not all has the ability to address the long term financial commitments and provides the security during the old age. Among them, the Employees' Provident Fund (EPF) which was formed under Employees Provident Fund Act 1991 is a compulsory savings scheme for those who are in Private Sector and one of the main objectives is to provide retirement benefits for its members. It acts as retirement savings for all those who are in private sector and manages the fund which is based on the income of individual savings and contributed both by employers and employees. In addition to this, EPF also ensures that the fund is growing over the years. The fund has three accounts, namely, Account I, Account II and Account II. Savings from all these accounts can be fully withdrawn when a member is deceased, incapacitated or leaves for permanent residency outside the country. Funds in Account I which constitutes 60% of monthly contribution is meant to be used after the retirement period and members are not allowed to withdraw until the age of 55 years old. Members are also allowed to invest a portion of their savings in this Account I in funds approved by the Ministry of Finance.

For those who are in Public Sector i.e. Government's servants have different type of scheme known as old age pension scheme under the Government Pension Ordinance 1951. This is a non-contributory scheme applicable to the employees of the government, semi-government agencies, local authorities and statutory bodies. It provides security for the retirement age. Civil servants are also entitled to receive the payment of gratuity based on the year of service. In some agencies, they are also eligible to receive certain payment known as a 'golden hand shake'. Hence, a considerable amount of savings is available for civil servants in addition to pensions. There is also another old age benefit scheme under the Armed Forces Fund Act 1973 but it is only for military personnel. Government has also introduced several schemes for those who are self-employed in order to assist the hard-core poor to venture into income generating activities through micro-credit facilities.

Currently these are the only social safety net available to give coverage for the old age. Recently EPF introduced a new type of saving called as PRS (Private Retirement Schemes). However, contribution for this fund is voluntary basis for those aged 18 and above and it is managed by private intermediaries approved by the Securities Commission of Malaysia. Since it is voluntary basis, not everyone has contributed to this scheme.

Since the time of establishment of EPF on the 1st of October 1951, full withdrawal age is maintained at the age of 55 whereas the life expectancy of Malaysians has increased to age 75. This means that the amount of EPF savings is not sufficient and does not last for these 20 years of old age.

2. Measures taken by Malaysian Government

EPF scheme does not cover to those self-employed, house-wives and without a fixed income. This category of people does not have a formal social safety net since they are neither covered by EPF not Pension Scheme for Public Sector Employees. Government has introduced 1 Malaysia Retirement Savings Scheme (SP1M) for this category people in order to get protection during their old age. This Scheme is designed to encourage this category of people to contribute voluntarily based on their affordability for their old age. The contribution can be as little as RM50 with a maximum amount of RM60,000 a year. Members of this scheme are entitled to receive annual dividend that is subject to a minimum dividend rate of 2.5% and eligible to receive Death Benefit (RM2,500) and an Incapacitation Benefit (RM5,000), subject to terms and conditions. To encourage saving, Government gives tax exemption up to RM6,000 per year (with life insurance) and contributes 10% per year subject to a maximum amount of RM120 per year. However, this contribution from the Government is only for the period of four (4) years beginning from 2014-2017 and limited to members below age 55.

In addition to this, Government has extended the minimum retirement age to 60 years old beginning from January 2013.

3. Social Security Net for Older People in Japan

The population in Japan has declined in recent years and the proportion of elder people has reached the highest level in the world as the life expectancy is high. Hence, the social security plays a vital role in maintaining the older people in the society. There are different types of social security system in Japan; pensions, health and long-term care insurance, public assistance, family policy, policy for people with disabilities and etc. and most of it adopt the social insurance system. The table below explains the social security for old age:

Scheme	Finance	Benefit		Type of Function
		In-kind	In-cash	
Public pension	Social insurance		In cash	Old age, survivors
Long-term care insurance	Social Insurance	In -kind		Old age

Table 1[iii]

The main characteristic of Japan's Social Security is that it is compulsory for all citizens to register in the public pension and health insurance programmes. Those above the age of 40 years old have to be covered by the long-term care insurance, and other employment related insurances; employment insurance and work-related accident insurance. These social insurances are to be borne by social insurance premiums and supplemented by the tax revenue in the forms of subsidy. The premium is paid by the insured based on their income. The rest of the schemes are financed from the public fund (Tax).

Public Pension consists of public and private pension schemes based on whether governmental or non-governmental servants. Pension system for those are in private sectors has three tires; Basic Pension, Employees' Pension Insurance and Optional Scheme.

The first tier, Basic Pension is universal since it covers all residents 20 years old and above. It is mandatory and provides a basic income guarantee for old age. The Basic Pension for those who are self-employed, farmers and unemployed is called as the National Pension and operated by the Government. The Premium for National Pension is paid by the insured only and is a flat rate for all. All of administrative costs and 50% of benefits are subsidised by the government.

The second tier, Employees' Pension Insurance is mandatory to all corporations over a certain size and the premium is shared by employers and employees. This is something akin to Employees Provident Fund in Malaysia. This covers most employees and the premium is shared by employers and employees based on the income. Both Basic Pension and Employees' Pension Insurance are operated by the government.

The third tier, Optional Scheme, is operated either by private corporations (employers) for their employees in the form of Employees' Pension Funds or by the National Pension Fund for those who are self-employed in which the government is the insurer. The Employees' Pension Funds unlike in Malaysia are operated employers and a large portion of it comes from the Employees' Pension Insurance. This Employees' Pension Insurance is the core of the income security for the old age and all workplaces with more than five employees are required to participate in this scheme. The premium has to be contributed both by the employers and employees based on income.
Whereas Pension System for civil servants is called as Mutual Aid Pensions which covers both Basic Pension; the first tier and the income-related; the second tier. In summary, the entire adult population of Japan is covered either by the Basic Pension and added by either Employees' Pension Insurance or the National Pension Plan for Public Sector and the Mutual Aid Pensions for Private Sector.

There are other types of personal pensions by private insurance corporations and trust banks, however do not fall under this category of a social security system and thus will not be discussed in this paper. A number of reforms have taken place in line with changing life-styles and continuing recessions of global economy affecting Japan. Currently 83.9% of Japanese corporations offer retirement packages for their employees. This package can be either in the form of one time lump-sum payment or a life-long or limited duration of payment.

The Long Term Care Insurance which is particularly designed to support for old age independence is user-oriented social insurance system. This provides coverage of comprehensive health, medical and welfare services. As stated above it is compulsory for those above the age of 40 years old to get insured. The insurers are those who have been engaged in health and welfare services for the elderly and expected to deliver services in harmony with community's social values. They play the role of collecting the insurance premiums, managing the fund, assessing the care needed and settling the payments to service providers. Hence they work with the government, prefectures, medical and pension insurers. There are two categories of insured; (i) those who are aged 65 and above; Category I and (ii) those who are 40 to 64 years old; Category II. Premium is based on income and there are measures to lessen the burden of low-income persons. Premium is deducted from pensions for Category I and from health insurance for Category II. The cost incurred in this Insurance is borne 50% by premiums and 50% by public expenditure.

There are different layers of social security provided for older people and yet the social security system in Japan has to undergone a number of reforms to meet the evolving needs and challenges faced by the older people in the country.

4. Findings and Recommendations

Retirement is an increasingly active phase of life where people should be taking personal responsibility for their own wellbeing by working, saving and looking after their health. If they have opportunities to continue contributing to society by working longer or volunteering in their communities, they should be doing so.

EPF was set up to provide coverage for people at their old age, it does not seem to fulfil the purpose. Sixty nine percent of EPF members aged 54 in 2013 are found to have savings below RM50,000.[iv] 50% of retirees have exhausted their EPF savings within 5 years. Majority of members have withdrawn their savings at the age of 55.[v]

EPF has introduced a number of initiatives to assist members to increase in their savings and discouraged members from depleting all of their savings in a short period of time. Under these new initiatives, members are encouraged to increase their savings in Account 1 from 60% to 70%. EPF also introduced the Age 55 Years Withdrawal, a flexible withdrawal facility that gives members the option to withdraw their savings lump sum or monthly, partially or a combination of the options and extended the contribution (mandatory) age from 55 to 75 for members who are still in employment. In January 2014, EPF revises the Basic Savings, setting RM196,800 as the minimum amount members should have in their EPF accounts then they reach age 55.

Despite all these efforts by the EPF, the research found that Malaysians do not have enough saving for their old age. Since the fund is compulsory only for those under employment and based on the income contributed by the employers and employees, unemployed and self-employed are not covered by this saving scheme. And hence unemployed and self-employed are left with no social coverage unless they have savings on individual basis. Even those who have EPF savings tend to use up their savings within first few years of withdrawal and resulted with no social safety net for them.

It is evident that EPF savings alone is not sufficient for a person to cover their old age. This insufficient savings for old age is as a result of a number of reasons; longer lifespan, low salary, early retirement, paying children's tertiary education fees and changing of social and economic trends and national development. Even if an individual with high salary having a big EPF savings may be left with a little amount of money at their old age since most of them have used up the savings for the education of their children. Hence children's education is one of the main factors in depleting the EPF savings for the old age. In addition to this, there is no other saving scheme like insurance based savings like in Japan unless it is initiated by an individual himself. Most of the time, people are unaware or do not realise the importance of savings for the old age. This factor is very crucial to those who are in the middle and lower income groups. Hence, accessibility to education is a very important factor.

Hence in addition to the current practice of EPF, there should an additional layer of social security scheme for old age by introducing savings based on insurance principles, something equivalent to what Japan has introduced to strengthen the social safety net for old age. At the same time Government needs to create more awareness on the importance of savings for the old age.

If insurance system is introduced, every individual who can afford will be covered under the insurance and this in turn will reduce the burden on the government and the government can provide a better quality service to those who cannot afford. Thus this will reduce the burden on the government and at the same time, it guarantees a better life for those who cannot afford it. There should be improvement in recruitment and retention of an aging workforce since working longer can benefit individuals, business, society and the economy. Government should set out new actions to heal people have fuller working lives. The role involves challenging outdated perceptions and making the case for older workers within the business community.

Pension age can help support the financial, health and social well-being of individuals into later life. It is important for the economy of the country, for employers and for individuals to make sure that old aged people can continue to afford pensions. Retiring at 55 instead of 65 could reduce an average earner's pension pot by a third- they would also have to spread this over a much longer retirement. By raising the pension age, it will help maintain a sustainable balance between the proportions of workers and retired people. We also have to remove the default retirement age, so in most cases employers can no longer force employees to retire just because they reach the arbitrary age of 65. Another way is helping older people get online to ensure that older people are not left behind and are able to benefit fully from the increased independence that comes with digital competence.

Since EPF is based on income contribution from employees and employers, those who are not working are normally not covered under this scheme. Though Government has introduced 1 Malaysia Retirement Savings Scheme for this group people, it is on voluntary basis and the participation is very low. Hence there should be one basic saving scheme who cover all citizens regardless their employment status.

In summary, it is recommended to introduce the followings to strengthen the current social safety scheme in Malaysia:

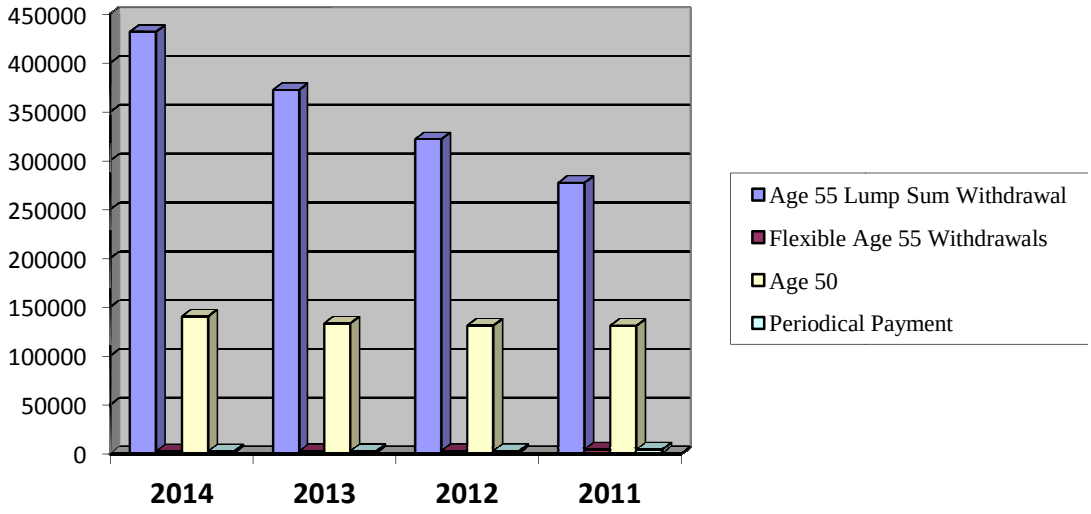
(1) Universal Basic Pension Plan: To make mandatory to all those above the age of 18 to be registered into a Basic Saving Plan like what Japan has introduced for all their citizens. With this plan, nobody will be left out from the social safety net for old age.

(2) Insurance Based Saving: This plan will an additional security measure in case there is no sufficient savings in EPF or the amount in EPF has been exhausted before the old age.

Introducing the above schemes into the existing social safety net will assist to lessen the burden on the Government in providing assistance to old age people and improve the quality of assistance provided to those needy people.

5. Conclusion

Malaysia may be headed for a retirement crisis as tens of thousands of Malaysians depart the workforce for their golden years with less saving than is needed to keep them out of poverty.[vi]



Breakdown of EPF withdrawals for the year 2014[vii]

Based on this statistic, it can be seen clearly that most members opted to withdraw whole sum of savings at the age of 55 and the percentage of withdrawal has been increased in recent years. Only less than 1% has opted for periodic payment over the years. Based on the Annual Report of EPF 2014, majority of members have an average savings of less than RM167,000 which is lower than the minimum saving level set by EPF at RM196,800. It is more alarming to find out that 69% of members have less than RM50,000 in their account and only 31% of members are still at work at the age of 54. Only 54% of members have less than RM20,000 in their account and evidently this amount of savings is not sufficient to support for 20 years after the retirement. In summary, most Malaysians do not have sufficient savings for their old age.

Currently only about 10 to 20 percent of Malaysians are considering non-mandatory retirement savings and investments to be added as a safety net for their old age in addition to their EPF contributions. EPF has implemented measures to enhance members' savings for their old age by increasing the mandatory contribution, introducing the PRS (Private Retirement Scheme) in 2012 as a voluntary long-term investment scheme for old age and encouraging members to opt to for flexible Age 55 withdrawal to choose partial or a monthly payment to lump-sum withdrawal of the savings. Still all these measures are not sufficient to shield the Malaysians during the old age and hence it is strongly recommended to introduce insurance scheme of savings like in Japan as an additional social safety net to strengthen the existing social safety net for old age in Malaysia. In addition to this, minimum wage should be increased and retirement age should be increased to 65 years old in view of increasing life expectancy and living cost.

Abstract (10 pt)

Change management and innovation is an important issue for the development of SMEs in Romania. However, only a few scientific papers in Romanian academic world address the subject of how resources and capabilities influence change processes and results small and medium family companies. We develop a series of postulates regarding peculiarities of change and innovation in these type of enterprises.

Keywords: entrepreneurship, change, innovation, family business

Introduction

Interest in small- and medium-sized enterprise family business continues to grow among academics as the dominance of family businesses on the economic landscape of most nations persists (Sharma, 2004), and the prevalence and importance of smaller family businesses is increasingly acknowledged (Le Breton-Miller and Miller, 2008; Richbell et al., 2006). In this paper, we are particularly interested in entrepreneurial SME family businesses and the critical role of innovation in such businesses (Kraus et al., 2012). Prior research has highlighted the necessity of innovation not only to recognize and exploit new opportunities but equally to refine current opportunities for the continued success of family businesses across multiple generations (Kellermanns et al., 2012; Naldi et al., 2007).

There are a number of research streams that have explored innovation within family businesses in various ways (Craig and Dibrell, 2006; Craig and Moores, 2006; Kellermanns and Eddleston, 2006; Kellermanns et al., 2012). Drawing on a developing body of work, we argue that there are some key differences between family and non-family businesses which may impact how such businesses innovate (Kraus et al., 2012) and that these differences may be further heightened within small- and medium-sized businesses compared to their corporate counterparts (Ceptureanu SI et al, 2015a).

The issue posed by Sharma and Salvato (2011) is particularly resonant to this paper: "What factors enable some family firms to display a remarkable agility in innovating in a sustainable way across generations?" This question has been explored by some researchers through the construct of entrepreneurial orientation (Nordqvist et al., 2008; Zellweger et al., 2010, Ceptureanu EG et al, 2012), by others considering specific sets of resources and capabilities within family businesses promote and/or constrain innovative and entrepreneurial activities (Sirmon and Hitt, 2003) and others specially exploring the notion of the family effect or "familiness" (Habbershon, 2006). According to Habbershon (2006), the social capital created by the notion of "familiness" is a key contributor to family businesses behaving entrepreneurially and innovatively.

More recently, Patel and Fiet (2011) have suggested, that family businesses have some particular advantages over their non-family counterparts with respect to discovering new opportunities through a combination of some of the common family business characteristics such as long-term orientation, low staff turnover, long leader tenure, and family ties that may lead to this advantage (Patel and Fiet, 2011).

This line of research inquiry encourages consideration of some of the business dynamics (even if arguably these dynamics might be influenced by something akin to "familiness") rather than the focus being primarily, or exclusively, on the family (Ceptureanu EG, 2015a). We argue that what is needed is an approach that does not privilege the family and/or the business or indeed the external environment when trying to understand innovation within entrepreneurial family SMEs (Nicolescu et al, 2009).

Theoretical Background

Innovation was identified by Schumpter as one of the key aspects of the entrepreneurial process. A Schumpeterian view of innovation focuses on how businesses manage their resources over time and develop capabilities that foster innovation (Schumpeter, 1934). Central to Schumpeter's theorising of innovation is the notion of combinations, whereby the "carrying out of new combinations" through existing elements or resources being combined or recombined characterises a Schumpeterian articulation of entrepreneurship (Schumpeter, 1934). Schumpeter emphasised the entrepreneur's critical role in the emergence of innovation within the economy, portraying the entrepreneur as the driving force of economic development and establishing them as the economy's innovator (Herbert and Link, 2006, Ceptureanu SI, 2015a). Entrepreneurial acts, from this perspective, put existing means "at the service of new ends" thereby introducing new combinations, otherwise referred to as innovations, which intermittently appear and herald economic change (Schumpeter, 1934). He describes five types of innovation as:

- developing a new good;
- building a new method of production;
- developing a new market;
- a new source of supply
- a new organisation of economic sector

Endres and Woods (2010) consider that "all acts with an entrepreneurial dimension must involve a process of conceiving new relationships ('combinations') between resources either given or changing, and ends either given or created a new". Galunic and Rodan (1998) posit that recombination's of firm resources either combine in such a manner that novel competencies are synthesised as a result (what the authors describe as synthesis-based recombination's) or result from existing firm resources reconfiguring in some manner. Family businesses, as mentioned above, can be considered as a unique bundling of two influencing systems - the family and the business (Ceptureanu SI, 2015b). As such combinations and recombination's towards innovation will likely involve both systems in varying degrees over time. Drawing on the conceptualisation of innovation as new combinations, we say that:

1. *Changes emerges in family business as a result of innovation*

Foster (2000) observed that Schumpeter's view of capitalist development as "non-linear and discontinuous" is due to the inability of entrepreneurs to determine long-term configuration stability within complex systems. This understanding of economic development resonates with characteristics of firm dynamics thinking whereby actors operate in open systems accommodating any number of elements that may influence innovation, including the environment and actors external to the immediate business. McCarthy et al (2006) argue that studies drawing on a firm dynamics framework enable the exploration of "how certain systems are able to learn and to create new rules, structures and behaviours [...] Characteristics necessary and important for systems concerned with exploration and innovation". However, it is often difficult to determine the border of a system (Cilliers, 1998). Within family businesses these "borders" are blurred due to the business and family systems interacting and overlapping

in unique and dynamic ways over time and across generations. Within these open systems, actors are unaware of the behaviour of all of the systems in which they are embedded and as such their actions and interactions are based only on the available information regarding their business context and other actors (Endres and Woods, 2010). There is no central controller, nor overall blueprint of the system to guide actors' interactions (Carlisle and McMillan, 2006). If an actor had absolute knowledge of the systems all of the complexity would be present in that actor (Ceptureanu SI, 2014). Arguably, absolute knowledge would in fact detract from an entrepreneur's innovative risk-taking inclinations (Endres and Woods, 2010, Ceptureanu SI, 2015a).

2. ***Innovation in family business is generated by family members***

Schumpeter's theorising suggests that entrepreneurial behaviour is conditioned by personal biography, tacit knowledge, and by the specific historic and social context of the entrepreneur, or entrepreneurial organisation (Schumpeter, 1934). This aligns with rules of firm dynamics thinking where Cilliers (1998) suggests history is co-responsible for present behaviour and evolution through time. Historical context can create conditions that lead complex systems down particular paths and influence interaction and adaption with business environments (Fuller and Moran, 2001). The social, business, family and individual contexts all influence the way in which an organisation and its actors interact, adapt and consequentially innovate. Actors will "experiment, explore, self-organise, learn and adapt" in response to changes in environments and contexts (Carlisle and McMillan, 2006). Furthermore, Schumpeter suggests that the development of case histories, biographical studies and profiles of both successful and failed entrepreneurial ventures in social and historical contexts are a revealing method of explaining the nature, scope and outcomes of entrepreneurial behaviour (Endres and Woods, 2010).

3. Innovation in family business is heavy influenced by the generational and social context

Becker and Knudsen (2002) summarised Schumpeter's view of the economic development as a whole, as "a phenomenon emerging on the basis of interaction among the various parts". Schumpeter explained that the dynamic interactions of entrepreneurs introducing new combinations causes disruption to the economy's equilibrium necessary for its evolution (Herbert and Link, 2006). Therefore to understand the development of the whole one must understand the interactions between the individual parts. Constantly adapting and seeking new sources of energy to force the introduction of new combinations, evolving firm dynamics operate far from equilibrium (Cilliers, 1998). Interactions between the elements of a system adapting to their environments encourage both self-organisation and change in the form of new combinations or innovation (Carlisle and McMillan, 2006). Such new combinations and/or innovation are critical to sustaining successful family businesses across multiple generations. However, Schumpeter's understanding of entrepreneurs' interactions promoting new combinations is presented at the macro level, investigating namely the resulting development of the economy. His theorising tends not to delve further into the how and why of entrepreneurial interaction that generates innovation (Endres and Woods, 2010). Foster (2000) suggests that complexity thinking, particularly the notion of self-organisation, is compatible with Schumpeter's intuitions of economic development and provides one way by which his notions of innovation can be usefully informed: "Combination" implies the deliberate formation and re-formation of cooperating groups engaged in production (Ceptureanu SI, 2015c). The result is expanding variety in products and processes (Foster, 2000). Goldstein et al. (2008) argue, from the perspective of firm dynamics that the entrepreneurial outcomes of an organisation emerge when interactions create a region of requisite complexity. Others have described this as a "zone of emergent complexity" (Carlisle and McMillan, 2006) or a "spiral of innovation" (Tapsell and Woods, 2010). Emergence then is the product of self-organisation whereby "experimentation, rule breaking, and exploratory actions [...]. can generate novel behaviours and [...] innovation" (McCarthy et al. , 2006).

4. Innovation in family business arises within the zone of complexity.

The preceding discussion has illustrated why and how postulates of firm dynamics can be useful for investigating innovation in entrepreneurial family businesses. We now turn our endeavour to exploring the suitability of some of the postulates of firm dynamics within the context of one specific SME family business. Highly relevant to this exploration is Fuller and Moran's (2001) claim that characteristics of firm dynamics resonate with the observed characteristics of SME's. Fuller and Moran (2001) argue that SMEs exhibiting entrepreneurial behaviour can resemble firm dynamics through their rapid adaptation within continually evolving environments. A complexity perspective is able to account for influences to SME family business innovation within its inherent elements including: internal and external actors, their interactions, the context and environment of the organisation and the open systems in which it is situated (Habbershon, 2006). Theoretical and methodological criticisms of firm dynamics research have been articulated elsewhere (McCarthy et al., 2006) and the conclusion drawn by various complexity researchers (McCarthy et al., 2006) that "case studies are well suited to capturing the rich and qualitative features of social firm dynamics" (McCarthy et al., 2006).

Conclusions

In the current turbulent and competitive global markets innovation is a means by which firms may not only stimulate growth and increase their competitive value but in some cases it may indeed be necessary for survival (Craig and Moores, 2006; Sirmon and Hitt, 2003). Yet to date, current family business research has only paid cursory interest to the area of innovation and lacks an organising framework or theory (Carr and Sequeira, 2007; Chrisman et al., 2005; Craig and Moores, 2006). In this paper, we have presented four guiding postulates based on firm dynamics thinking, within which notions of innovation are inherent. The four guiding postulates present a holistic understanding of innovation, a key characteristic of complexity thinking, in both SMEs generally and specifically family business SMEs. In applying the guiding postulates to our case study we demonstrate their ability to account for the unique influence family dynamics or "familiness" has on innovation which has often been overlooked in family business research. We argue that the interconnected nature of our guiding postulates presents a useful understanding of the influences bringing about new combinations and also illustrates how the combining of "family" and "business" can characterise SME family business innovation and provide practical insights for family businesses experiencing intergenerational transition (Ceptureanu EG et al, 2014). Through applying these postulates we believe we have also made steps towards demonstrating the benefits to SME family business of operating according to firm dynamics rules. Understanding the dynamical nature of systems change or what Goldstein et al. (2010) describe as bifurcation, in family business contexts refers to both the family and business systems, allows greater depth of exploration. The systems can be simultaneously understood from both a stability and/or instability lens and the dynamics and change between and within system opportunities and constraints can be explored (Shepherd and Woods, 2011, Ceptureanu EG, 2015b). Such an approach encourages attention to be paid to the parameter changes and the implications this has on innovation. In the case example above, these changes were both family related and business related. We would suggest that this line of inquiry is rich for further research (Ceptureanu EG, 2015c). For an organization to succeed in these turbulent times and achieve incremental and/or radical innovation they must foster a culture and processes that promote flexibility in their responses to internal and external environments (Carlisle and McMillan, 2006; Ceptureanu EG, 2015d). Operating with an understanding of the rules of complexity thinking provides a lens for exploring how SME family business can innovate and prosper across successive generations and live with the limited control and unpredictability of the current business environment (Regine and Lewin, 2000). SME family businesses who understand their organization as operating according to complexity rules may be better placed to work with change and the processes that underlie such a system (Regine and Lewin, 2000, Ceptureanu SI, 2015d). We suggest that a Schumpeterian and complexity perspective on innovation offers a lens which encourages consideration of both positive and negative loops within the dynamic

systems of both the family and the business over time and this would be a fruitful area for further research to pursue. Additionally future research in the area of family business innovation could be well served by exploring networks and both strong and weak ties and their influence on the innovation systems. The so-called six degrees of separation between people is quickly reduced to two or three. What are the implications of this type of influence on getting independent thinking and advice into the systems? How do outside advisors, coaches, directors and/or mentors influence the business and family dynamics? Finally, the question of how family business actors interact and act entrepreneurially and innovatively with only limited knowledge of the systems at any given point in time might also is an interesting avenue for further research (Ceptureanu SI et al, 2015b). We have argued the rules offered here may contribute a broad foundation for developing an organising framework investigating SME family business innovation (Ceptureanu EG, 2015e). Indeed, Fuller and Moran (2001) suggest that a firm dynamics approach may offer an integrating framework providing the potential for convergence between other theories.

Abstract

The article deals with the stability of the domestic economy in the context of the main problems of the Russian banking system which developed in a period of transition to a market economy, as well as after the economic crisis of 2008. The authors paid particular attention to the readjustment procedure for the authorized commercial banks in the mode of recovery of economic subjects of the market of banking products and services. This is because of the extraordinary role that the banking system under the control of a mega-regulator plays in the functioning of the institutional economy and, in particular, of the real sector of the economy. The banking system, however, is currently demonstrating its own compression at an alarming rate. The authors are trying to obtain an understanding of the problems that are common to the withdrawal of the Russian industry from the recession. For this purpose, according to the authors, it is necessary, first of all, to develop a proper rehabilitation scheme directly for the Russian banking system largely blocked by financial institutions which are the least concerned about the interests of the national economy. A renovated banking system, according to the authors, is capable of providing investments in the fixed capital of industries of the real economy in the required quantities. The available credit facilities will enable industrial enterprises to get out of the sleeping state and properly solve the problem of actual import substitution.

Keywords: real sector of economy, stability of economic institutions, industrial production, banking system, authorized commercial bank, readjustment, monetary aggregates, credit rate, resistance, withdrawal of license, discount, object of property, sources of economic growth.

In fact, God is on the side of the biggest bank accounts.
Adam Smith

Introduction

According to the findings of the report of the Ministry of economic development of the Russian Federation "The development trends of sectors of the economy, in 2015", in that year production went through an extensive decline in a wide range of sectors of the economy. The greatest reduction occurred in the sectors oriented to domestic demand, especially those of the manufacturing industry that creates a high added value. The only exceptions were agriculture, food production and chemical industry; growth was observed mainly in the export-oriented raw materials industries the main commodity-oriented industries aimed at the production of oil, gas, coal and metals (see Table 1).

Table 1: The structure of industrial production in the Russian Federation, %

№ п/п	Sector of the economy	2013	2014	2015
1	**2**	**3**	**4**	**5**
1	Fuel and energy complex	47.8	48.1	46.0
2	Sector of investment demand	18.1	17.9	17.3
3	Sector of intermediate demand	21.5	21.3	22.9
4	Sector of final demand	11.4	11.5	12.6
5	Miscellaneous manufacturing	1.2	1.2	1.2

However, the decline in raw material prices was so substantial (according to the Central Bank, just the export prices of oil, gas and petroleum products decreased in 2015 by 57.5 per cent) that the value of their share in exports decreased from 69.5% in 2014 to 62.9% in 2015. However, due to a smaller reduction of prices on other goods, their share has grown, even though in monetary terms the supply was less than last year. For example, the share of engineering products in exports increased from 5.3% to 7.4%, and of wood and engineered wood products from 2.3% to 2.9%.

The specifics of this period, which is defined by certain prominent economists as the change of yet another technological paradigm, when a post-industrial economy has to be immediately replaced, allegedly, by an innovative economy, is in the failure of the market mechanisms predicted by none of the theorists. Since the trends of global instability and poorly predictable price and exchange rate volatility also affect the national economy, the market becomes, so to speak, temporarily short-sighted.

Accordingly, since the balancing equation must be satisfied, the role of the state and paternalistic attitudes dramatically increases in this situation that is no longer quite market. It is the state that now carries the main burden in initiating the widely discussed and planned the large-scale restructuring of the national economy, or the new industrialization or re-industrialization, etc. 1, in Russia, and, while the country was recently recognized as a superpower, it is currently classified by the world's three leading rating agencies (Fitch Ratings, Moody's Investors Service, Standard & Poor's) in a group of countries bashfully called developing.

These circumstances determine the urgency of the questions touched upon in this article and widely discussed in the scientific community, including by the professionals listed in the bibliographic list of used literature, and also in the works of other famous authors not included in our review.

Is the State a "Night Watchman" of the National Economy or the Visible "Hand of the Market"?

How to interpret such an involuntary increase of the state's role in market realities? World experience of previous similar financial crises shows that a window of opportunities indeed opens for the developing countries wanting to profit from a new wave of economic growth. However, to 'open' this window, it is necessary to have the rate of accumulation not at 20-23%, as is the situation in Russia, but to strive to attain a 35-40% savings rate to Gross Domestic Product (GDP). Since the market itself cannot generate such a huge momentum, direct state intervention into the mechanics of the inevitable capital grown is necessary.

Taking into account the direct intervention of state institutions in the process of restructuring, the banking sector should play a special role in implementing the future structural changes. Indeed, if we consider the potential sources of financing, those presented by the fiscal mechanisms are not great,

[1] These terms are now widely discussed and commented upon in the scientific community.

but there are enormous opportunities presented by the monetary mechanism. However, there are no workable mechanisms for financing economic growth through a system of the Russian Central Bank (CBR) because they are not clearly described in the founding documents. The mechanisms of the lending schemes of structural changes and the long-term target programs and projects were also not set.

Federal Law on the Central Bank, of course, should be improved further, as the main Russian regulator (megaregulator) is not responsible for the economic performance of the country as opposed to, say, the Federal Reserve System (FRS) of the USA2, whose regulatory documents explicitly describe this dynamics. The provision is especially well detailed as a doctrine in the statutes of the 12 regional offices of the authorized banks of the Federal Reserve as maintaining a balance between the interests of commercial banks (CBs) and key national interests.

But the role of Russian banks as a driving force of the economic development of the country, aside from the above-said, is significantly complicated by the quality of the financial services rendered to the clientele and to consumers in the broadest sense. The discussions at the World Economic Forum in Davos in 2013 ranked this quality around the 60th place in the world, between Colombia and Venezuela, and actually after Ukraine.

These circumstances are directly related to the specifics of the monetary policy which has been carried out in the last 17 years in our country. Money supply is issued primarily for the purchase of foreign currency (in Central Bank of RF currency interventions mode), so all serious bank loans are either state-owned bank products (more precisely, of the banks with state participation), or foreign loans which are digested by the Russian non-state (authorized) commercial banks.

However, since the early 2000s, we observed the opposite process of a multifold growth of Russian direct investment flows abroad credited by the domestic banking system and having exceeded $70 billion in 2012. Already in 2014, as reported in the Deposit Insurance Agency (DIA) report, Russians took 1.3 trillion rubles away from the banks. However, during the same year, household deposits in banks increased by 9.4% to 18.55 trillion rubles, but this increase was achieved entirely due to currency revaluation.

The Interest Rate – The Price of Credit

While Russian banks' profits for the same period grew continuously, as analysts, we cannot precisely congratulate the domestic bankers on their success, as these record results were obtained mainly due to the inflation of credit rates (congruent with a key rate of the Central Bank), driving the rest of the economy into depression. But the development of relatively new (and at the same time relatively old) credit facilities is not a cure-all for the economic development of the country; here the positive experiences of Germany, America, and China should be noted, with banking using project financing, rather than the universal principles of lending, as the driving force practically everywhere.

According to mass media and respectable economic journals, $ 600 billion is needed for modernization, reconstruction or new industrialization of the national economy. However, as $ 500 billion were already taken abroad by Russian borrowers, the question arises whether our money economy and the monetary authorities could generate the same amount of credit supply, which is now actually transferred to foreign sources of credit, as Prof. O.G. Dmitrieva3 constantly writes and speaks convincingly.

[2] The Federal Reserve System, FED – created 23 December 1913 as an independent federal agency to carry out the functions of the Central Bank of the United States, and the implementation of centralized control over the commercial banking system of America.

[3] A trustworthy author proves that the escalation of Russian debt, along with the the replenishment of the Reserve Fund and National Welfare Fund, leads to the imposition of the negative effects of surplus / deficit

An extremely important issue for the entire Russian economy is the assessment of its prospects for sustainable development, including its most important sector, the banking system. The stability of the banking sector and the possibility of improving the banking system as a whole depend on the solution of this problem. Terminologically speaking, compared with stability and reliability, sustainability is a broader concept and involves a complex of conditions and measures through which a financial and credit organization performs its functions and fulfills its obligations to other entities with which it interacts in the marketplace and in the financial markets.

Ways to improve the effectiveness and efficiency of the banking system in the aftermath of the international financial crisis can be found through the detailed study of global trends and patterns of development of the banking business, their sound projection onto the Russian economic reality and skillful adaptation of trend effects to the constantly changing conditions of the banking environment and the inflation that has become very noticeable in 2015. Characteristics of the last components are reflected in Fig. 1, and the combined indicator is rapidly approaching the parameters of the inflationary dynamics of Belarus and Ukraine (see Fig. 2).

The following global trends in the banking sector can be highlighted as an illustration of what is happening: basing all activities on the most modern IT-technologies; non-stop improvement of the traditional and the introduction of new techniques and methods of interaction with customers and providing them with the entire spectrum of banking services (expansion of supermarket chains, banks, installation of multimedia kiosks, machines, the use of the global Internet, and so on); as well as the intensification of banking activities in the markets of securities, precious metals and real estate.

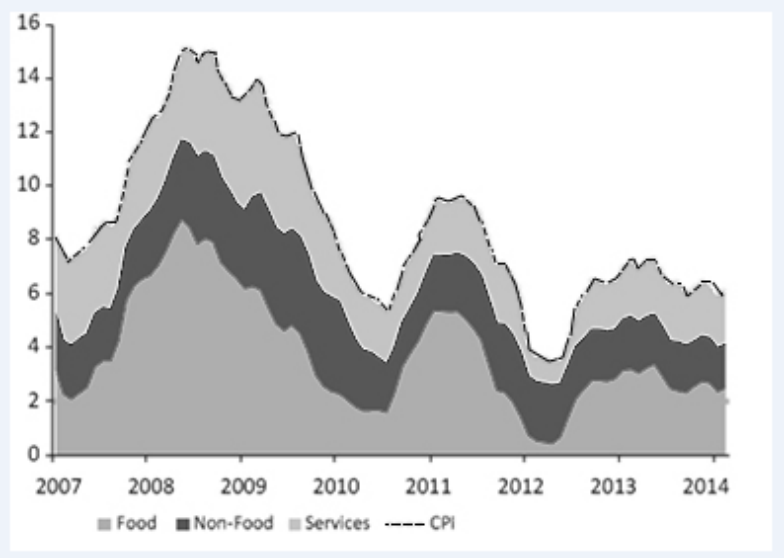

Fig. 1. The dynamics of the inflationary component in RF for the period 2007-2014, %: the dark gray area is the food component; black is the non-food products; light grey is the services; the upper dotted outline of the light-gray area (dark dotted line) is the monitoring of the Laspeyres price index (CPI) for the period. Data source: estimates by Rosstat (http://www.gks.ru/) and experts from World Bank (http://data.worldbank.org/) as of 01.03.2015

budget, i.e. artificial deceleration of economic growth accompanied by a dramatic increase in government debt and its servicing costs.

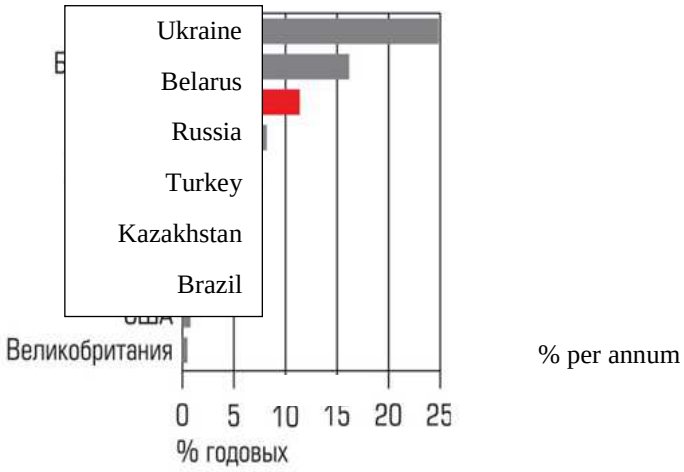

Fig. 2. The distribution of individual countries in the growth of the CPI in December 2014, %. Data Source: Rosstat (http://www.gks.ru/)

One of the key Russian trends for 2014, as claimed by the chief economist and well-known strategist of Deutsche Bank J. Lissovolick, was the consolidation of the banking sector, reorganization and revocation of licences from unscrupulous commercial banks (CBs). Another important trend last year was an attempt to cool the Central Bank of RF rate of retail lending in the country, which took place against the background of the continuing growth in the volume of "bad" (also known as "toxic", also known as "poisonous") debt4. In our opinion, in 2016, the same as in the previous year, the Central Bank will continue to actively and consistently withdraw licenses from banks but will far less regularly send them to reorganize.

Meanwhile, the situation in the credit market continues to worsen. At the beginning of February 2015, the citizens of the Russian Federation owe a total debt of more than 11 trillion rubles, 730 billion of them in overdue payments, while 89% of all debt are consumer loans, the shortest, most unsecured, with the highest percentages. The rest are mortgage and housing loans; debts to banks exceeded the level of the 2009 crisis.

Financial pyramids may continue to grow on the banking market by the REPO scheme (from repurchase agreement, or repurchasing operations); the sizes of these are already at record levels5. It

[4] Currently the idea of creating in Russia a special bank for bad debts on the basis of Vnesheconombank is discussed, using debt repurchasing in South Korea after the crisis of 2008-2009 as an example, as well the situation in post-crisis Ireland. Thus, VEB could turn into a kind of mega-collector.

[5] REPO is the form of the transaction in which securities are sold, and at the same time an agreement to repurchase them is concluded at a pre-stipulated price and time, i.e., repos are an instrument of liquidity of the banking sector, against securities. Reverse repurchase agreements (reverse repo) are the purchase of securities with an obligation to resell. Thus, the repurchase agreement is a transaction of two types: an operation with cash securities today, plus a forward contract for the same assets in the future. At the beginning of the trading day on 01/04/2014, the total debt to credit institutions to the Central Bank repo transactions amounted to 1 trillion 936 billion 301.8 million rubles.

Repos are carried out on an ongoing basis by the Central Bank every working day at fixed interest rates. Repo auctions with a minimum rate are held by the approved schedule.

A year later, the total debt on direct repo transactions to the Central Bank at the beginning of the trading day on 01/04/2015, respectively, increased to 2 017 793 400 000 rubles at the beginning of the previous operating date, which follows from the CB RF information. CB RF requirements for credit organizations on separate agreements to repurchase at a specified date officially are: Operations on an auction basis – 1 910 803 600 000 rubles; operations with fixed rate – 106 989 800 000 rubles.

is estimated that the share of the Central Bank of RF in liabilities of the banking sector exceeded 11% at the beginning of 2015. Fig. 3 shows fragments of how the events developed using the direct REPO financial instrument up to this point.

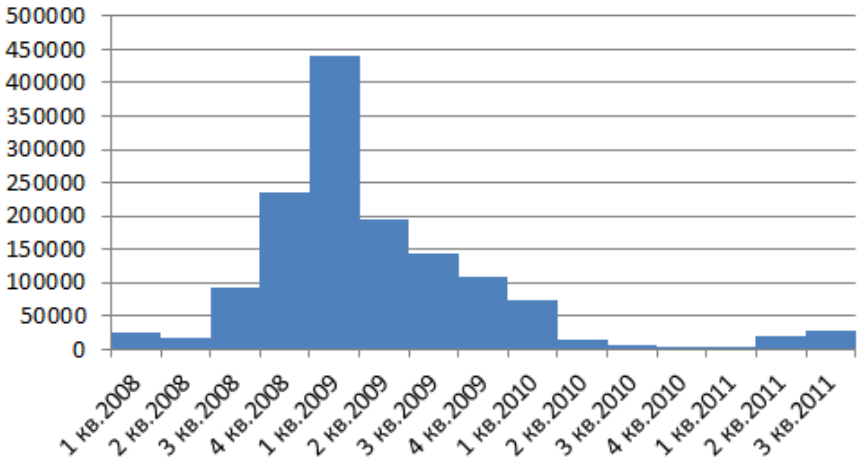

Fig. 3. Debt on repo transactions to the CB RF, on a quarterly basis for the 2008-2011period, mln rub. Data source: Central Bank of RF

By the beginning of May 2015, the share of overdue bank loans rose to a record 7.22%, reaching 780.6 billion rubles, despite the slowdown in lending. Since the beginning of 2015, overdue debts increased by 17.0%; in a year (from the end of April, 2014 to the end of April, 2015) they grew by 1.5 times, as indicated in the review published by the largest collection agency Sequoia credit consolidation: "In 2009, the share of overdue debt did not exceed 7.0%" that generally corresponds to the values in Fig. 4.

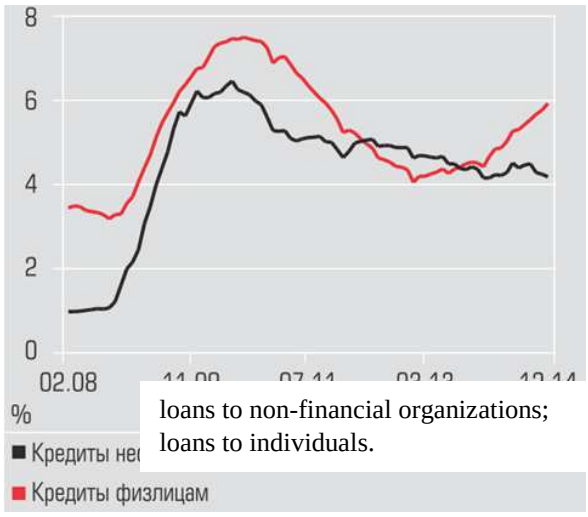

Fig. 4. The share of overdue loans to non-financial organizations and individuals for 2008-2014. *Data Source*: Central Bank of RF.

Reducing the Number of Credit Institutions in the Banking Market is a Customary, Forced Trend that is Nevertheless Gaining Momentum

The banking community expected to lose 33-35 licenses in 2015, as voiced by the corresponding member of the Russian Academy of Sciences, President of the Association of Russian Banks, G.A.

Tosunyan (in his speech on April 4, 2015 in St. Petersburg at the 6th International Scientific and Practical Conference "The architecture of finance: geopolitical imbalances and the potential for development of national financial systems", in which one of the authors of this article participated), although as of 11.18.2015 there were 82 lost.

In 2013, 44 licenses were revoked from credit institutions, and 95 in 2014, which is the highest value since 1999, so it is clear that this process is accelerating, and "harmonization" of the banking system and the new market restructuring inevitably lead to a further transfer of contributions of individuals to the accounts of major banks. These banking institutions are the beneficiaries of all sorts of gains from the difficulties of the current economic situation, while medium and small-sized organizations are forced to consolidate their activities in various ways to stay in the market. There was a total of 11 recorded rehabilitations of commercial banks in 2014, which is very little. The overall dynamics of this process in the banking market is shown in Fig. 5.

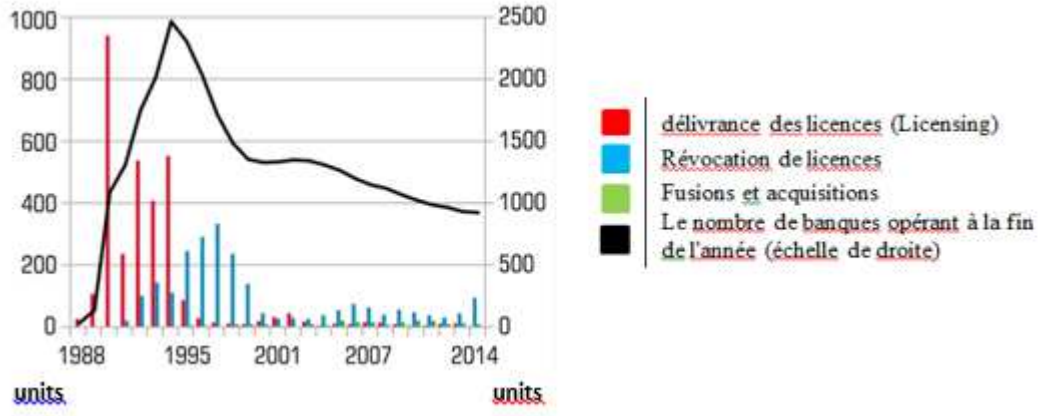

Fig. 5. The movement of credit institutions in the banking market of the Russian Federation for the period 1988-2014. Data Sources: CBR; Calculations AC "Expert Ural» (http://www.expert-ural.com/analytics/), 2015

As for the industry average debt level, in a noticeable number of activities it came close or exceeded the safe level specified as a 5.0-fold magnification.

The main cause of the events is the particular current state of the national economy, which is exhibiting signs of a recession, i.e., a special pattern of the decrease of growth rates of macroeconomic indicators. In connection with the withdrawal of licenses from many KB, the inflow of deposits in "almost" state-owned banks and banks with state participation has increased significantly, as, respectively, has the area of banking credit and financial operations.

The Practice of Appraisal Activities of Banking Institutions in Their Liquidation, Mergers and Acquisitions

Consolidation is an important tool in managing the transformation of the banking sector, and the frequency of use regulator of the instrument is the main indicator of the state of the sector. Such a tool has traditionally turned into an instrument of the monetary authorities at a concentration of banking capital. Most experts, both domestic and foreign, is associated the concept of "consolidation" is a mergers and acquisitions.

As a result, taking into account and coordinating the existing positions of various experts regarding the economic substance of consolidation, it is possible to reach an intermediate conclusion that consolidation is a process in which the merging and consolidation of the banking businesses occurs through acquisitions and the merging schemes of independent banking institutions. However, it

seems to us that these processes require close supervision by the government and content analysis conducted by the scientific community.

The need for market assessment of the banking business, assets and liabilities of financial institutions arises in cases where they become potential or real objects of market processes and transactions, i.e., purchase, sale, liquidation, privatization, corporatization, transfer in trust, etc. Specifically, business assessment of an individual CB is necessary for selecting the options justifying its restructuring, for improving the efficiency of its asset management and for maximizing its total value and the usefulness of a particular banking institution for the financial market.

The peculiarity of the market valuation of the CB is that it is carried out at the junction between the theory and practice of credit and banking and assessment of banking institutions. In this regard, one of the theoretical issues becomes identifying the essence, content and forms of expression of such economic categories as the market value of the economic entity in relation to the traditional banking structure. While there is some accumulated experience of calculating cash flows, forecasting income and expenditure, determining the discount rate to evaluate the CB as an integrated business, assessing its tangible assets and certain types of intangible assets, analog selection, etc., the acceptable methods of assessing the cost of the specific bank assets are still in need of further theoretical and practical development.

Consolidation of economic entities of the banking sector can be seen as the process of unification and enlargement of the credit institution's capital, as a certain stage of development of the latter when the development of bank strategy is caused by diverse factors taken into account in the analysis. These factors can be internal, such as the achievement of synergies and external factors of different risk levels, for example, political. Other external factors may include economy- and industry-scale factors, as well as legislative initiatives.

Thus, to counteract the activities of unscrupulous banks, on November 23, 2014, the President of the Russian Federation signed amendments to the Federal Law “On Mortgage (Pledge of property)” no. 102-FZ of 16.07.1998. These amendments provide for the repayment of a recording made on the basis of the statement of the pledgee, in the case of the sale of collateral through foreclosure in court. That is to say, the 2014 version of the "On Mortgage (Pledge of property)" law emphasizes that if the borrower refused, for any reason, to pay the mortgage, then, upon application of the lending bank, the mortgaged property can be put up for sale. Moreover, if the parties mutually agree, the property mortgaged through the imposition of a penalty may be put up for sale at a price less than the one indicated in the contract of mortgage lending.

According to banking experts, this form of auction contributes to greater economic results in selling mortgaged property in the time of crisis. In addition, it increases the interest of the mortgagee to the use the market mechanism for selling the property, which has a positive impact on the development of mortgage finance. In other words, the amendments to the federal law established and included in the legal framework as a norm for the convenience of both lenders and borrowers. When property prices fall, selling residential premises even by the residual credit value, i.e., subtracting the sum that the borrower has already paid, still exceeds its market value during the crisis.

In addition, changes in national legislation clarify the features of the mortgage of buildings and other non-residential premises. By law, real property is transferred as collateral only if the property right of the person concerned has already been registered. However, the explanatory note to the regulatory document does not ensure the full protection of the legitimate interests of the creditor with simultaneous registration of title with encumbrance in the form of collateral, even though such a procedure is provided in relation to housing mortgage. In particular, the objects of housing stock and land, acquired at the expense of the bank, are pledged from the date of registration of property rights. In this case, the interests of creditors are protected under the Act.

Will the Market Prefer Resolution or Liquidation of Cbs? or is it actually State Business?

One of the most important functions of managing the economic entity is the financial analysis revealing abnormalities in the development of the subject under study that in some cases requires its resolution instead of elimination.

The aim is to cover the financial rehabilitation of the current losses and to eliminate their causes, renewing or maintening the face-liquidity and solvency of the CB, reducing all types of debt, improving working capital structure and forming financial resource funds. Resolution plays an important role in the system of stabilization measures aimed at leading the CB out of the financial crisis. From a legal and a technical standpoint, resolution is a system of measures for the financial rehabilitation of the CB, implemented with the help of individual or legal third parties, and aimed at preventing the CB from being declared bankrupt and from elimination. Today, every sixth CB is a candidate for resolution due to their insurmountable inprofitability and/or chronically low profitability, which is illustrated in Fig. 6.

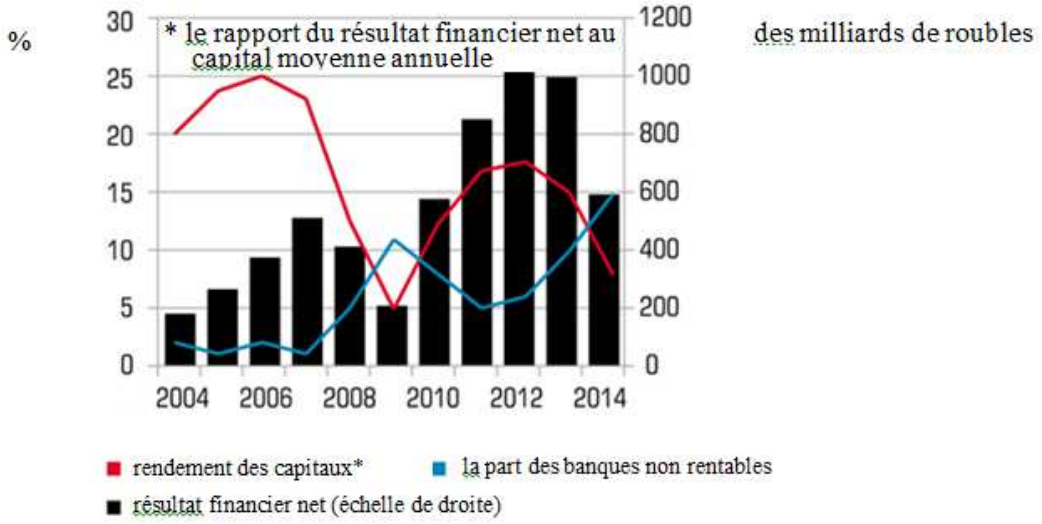

Fig. 6. Mass of the rate of profit in the banking system of the Russian Federation for the period 2004-2014. Data Source: calculations of the Central Bank

At this initial control stage, based on the results of diagnosing bankruptcy and monitoring the implementation of measures to stabilize the internal financial conditions of the CB, a fundamental decision is made to perform resolution. The feasibility of the resolution is caused by the fact that the use of internal mechanisms of the CB's financial stability do not always reach their goals, and the CB's critical financial condition continues to deepen. Indeed, as noted by Sberbank's experts, in the short-term forecast period, the amount of toxic debts in the segment of ruble corporate loans will reach its peak by the middle of 2016, and the projected level of the delay will be even higher than in the previous crisis of 2008, as shown by dashed lines in Fig. 7.

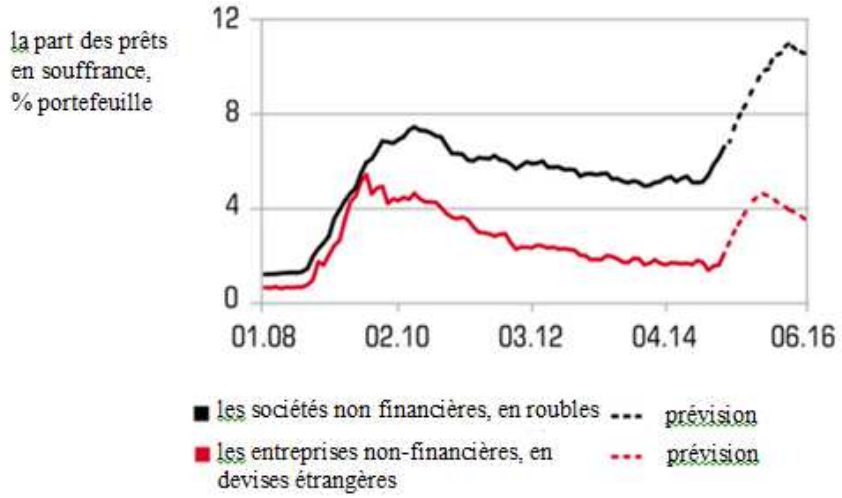

Fig. 7. Analysis and Forecast "bad debts" in the segment of ruble-denominated corporate loans over the period 2008-2016. Source: calculations and forecast of M. Matovnikoff (Savings Bank of Russia), according to the Central Bank of the Russian Federation

Sources of Investment and Other Means Necessary to Ensure the Development of Industrial Production

An increase in the key rate of the Central Bank of the Russian Federation, as well as its energetic measures for shrinking the liquidity in the economy that has made financing economic growth unprofitable and difficult resulted in a slowdown in economic growth and stagnation. Therefore, the transition to stagflation was a natural with such a policy and was caused by internal reasons.

This ugly structure of our economy was the main reason for the significant devaluation of the ruble against the dollar and the Euro. Here the ruble has been devalued by around 1.5 times, which correlates with a corresponding decrease in oil prices. Further factors were the accelerating inflation, sanctions and inept monetary regulation by the Central Bank of RF. The current recession, and stagflation mean a structural crisis, the root cause of which is inadequate economic policy. A structural crisis associated with the stagflation lasts much longer, and the exit from it is much more difficult and painful.

The situation with inflation is particularly bad: it has increased significantly in recent months due to the devaluation of the ruble and the increase in utility prices, so the Central Bank of RF stopped decreasing the key rate, which continues to stay inaccessible for businesses and organizations, as well as the population. Because of this, for the first time there has been a reduction in the volume of lending and the national economy, and in population. Credit debt of companies and organizations to domestic banks rose to 30 trillion rubles, which is several times higher than their annual profit. Debt reached 11 trillion, or almost 30% of their annual income. The final consumption of households in Russia decreased dramatically to 9% in 2015, and the demand turned from the engine of the economy into its brake.

Project financing is an important stimulant of investment in the implementation of large investment projects, offering investments for projects, and not secured by property. This important initiative of the President has acquired such bureaucratic regulations, micromanagement, low guarantees allocated, that in real life it had no impact on investment activity at least in 2015.

The transition to forced investment, supported by encouraging economic growth along the main directions of these investments in institutional reform, is at the heart of the new economic policy. The condition for transition to forced investment is the implementation of the program for the drastic

reduction of inflation and key rates of the Central Bank of RF. The inflation rate and the key rate, according to RAS member A.G. Aganbegyan, could be reduced by three times in 3 years, i.e., up to 4%.

Another important condition for the implementation of the policy of forced investment is the elimination of barriers to economic growth, which involves the implementation of structural institutional reforms gradually, step by step. The country's financial system needs to be restructured with a higher proportion of "long" money, which can serve as investment funds. In this regard, the work of the stock market needs to be radically reconstructed, as it must be turned into a channel for capital formation and flow.

It is more logical and easier to draw these funds from the assets of our banking system, the amount of which as of January 1, 2015 amounted to 77.7 trillion rubles and for the first time in 2014 has exceeded gross domestic product. The amount of bank assets are 2.5 times higher than all the annual funds of our state presented in the consolidated budget, including state budget funds. The assets of the banking system are five times greater than the volume of the Federal Budget. Although the proportion of the consolidated budget in 2015 was approximately 40% of the entire GDP, it contained only 18.5% of all investments, and this percentage is constantly declining.

As a result of the author's analysis of the banking industry, since 2008, i. e, during the so-called turbulence, we can draw some conclusions, directly related to the possibility of econometric modeling for the implementation of predictive calculations macro indicators of the national economy. According to the facts set out in the article, you can select some of the most significant factors, one way or another related to the banking services market, and for which you can perform a statistical analysis of the sensitivity to the selected performance indicators.

In other words, there is a technical possibility of building econometric with the inclusion of the planned features of factors in the dynamic multi-factor model using the correlation parameters, such as the net coefficients of elasticity for such performance indicators as GDP, the volume of investment in the real economy, the level of employment in the labor market, nationwide inflation rate, the size of the backup in the banking system, the volume sold in consumer demand of households and population through retail sales, as well as other important nominal economic activity indicators.

The first factor is directly related to inflation, which determines the cost of capital in structuring transactions. With high inflation seriously evaluate the cost of capital even in the medium-term forecast horizon is not possible. If the inflation rate will reach 4%, which is projected mega-regulator by the end of 2017, the Russian company will be able to confidently make plans for borrowing in the credit markets.

The second factor – the cost of debt financing (loan price). Today on the key rate of the Central Bank 11%, taking into account the cost of risk, the cost of loans to CB services of any investment projects as it is virtually impossible, since such a rate is dissuasive for the overall investment climate6. There are plans for the Central Bank at the end of 2016 to reduce the key rate to 6.5%, but provided a commensurate reduction in inflationary pressures nationwide level to 4-6%, has already stretched for two years.

The third factor relates to the fact that by the end 2015 71% of Russia's GDP (already on a new methodology SNA) formed by consumption, with 51% of the consumption of households and population. And if in 2011-2013 the domestic economy grew at an average annual rate of 5%, this

[6] The high cost of loan capital, however, varies depending on the type of borrower. According to CBR statistics, in 2014 the average interest rate on loans was as follows: for large enterprises – 15.8%, for small and medium-sized enterprises – 17.3%; and in 2013 – 11.4 and 14.2%, respectively.

consumer demand, as the authors believe, has been the main driver of economic growth. In the period 2014-2015, GDP went down, and therefore unsatisfied customer demand accumulated.

The fourth factor – this is quite a strong statistical relationship between the level of the price per barrel of the reference mixture of Brent crude oil (p), by which is designed, in particular, the prices of three of the five Russian export brands Urals, Siberian Light and REBCO and the exchange rate of the ruble (RUB) the dollar (RUB/$). According to the author's estimates, the simple correlation coefficient of these indicators during 2015 had a probability of 0.954 variability in the range of 0.917 $\leq r_{rub|p} \leq$ 0.936.

Conclusions

1) For all the imbalances and shortcomings of Russia's economic development, the country has certain capabilities and impressive potential, the use of which in the transition to a new economic model, more efficient state regulation of investment-innovative processes and sound management of structural changes in the mode of reform will provide the real acceleration of the socio-economic development of the country.

2) A mechanism for achieving the main objectives of the resolution is characterized directly by its form chosen from the recommended broad spectrum. This form can be adjusted in a specific direction of the resolution elected by the CB. For example, resolution aimed at refinancing the debt of the CB can take these forms: state concessional lending; target bank loans; transfer of debt to another entity.

3) If the power structures really have the intention to create a workable funding mechanism of progressive structural changes in the Russian economy, it is necessary, first of all, to pay attention to the improvement of public credit facilities and refinancing of CBs, as well as to introduce a flexible system of money supply with the regulating role of the interest rate, i.e., the loan rate. The most important role should be played by real development institutions that have clear plans and accountability mechanisms for achieving these plans. Therefore, it is necessary to improve the legislative and regulatory practices regarding the economic relations in the Russian marketplace.

4) In this sense, the legislative initiative of the Ministry of Finance of the Russian Federation making a number of amendments to the Federal Law "On Banks and Banking Activity" at the end of June 2014 is noteworthy. The amendments state that the state-owned companies and public corporations, many private institutions and retail chains are allowed to open accounts and deposits7 only in the state bank and in VEB, as well as in Russian private banks (alimited number of CBs) with a net worth of not less than 16.5 billion rubles, which is clearly paternalistic in nature, aimed at protecting the funds of the Russian stragegic companies, preserving business in the real sector of economy, and at protection against possible sanctions.

5) Furthermore, the efforts in increasing the integrity of the state funds in Russian banks, initially started with the intention of clearing the banking sector from unfair participants, will be completed by 2017. As of January 1, 2016, there were 733 credit institutions in Russia; in a year, their number dropped to 101. For comparison, in 2007 the country had more than a thousand CBs.

Mass closure of CBs began in 2013. The Central Bank of RF decided to improve the banking sector by removing credit organizations with suspect activities from the market. Most often, the licenses were revoked for breach of normative acts of the Central Bank of RF, anti-money laundering legislation and for carrying out highly risky credit policy.

[7] In 2013, the state-owned companies placed 720 billion rubles in bank deposits. In late 2013, the megaregulator acted as a driver for tightening the criteria for the selection of credit institutions for placement of state company funds, due to the fact that the Housing and Utility Reform Foundation, a state corporation, lost as much as 1.5 billion rubles in the seemingly stable Investbank.

Summary

In view of searching for ways of improving the Russian banking system as a whole, increasing the stability of individual CBs and leading the national economy out of recession, there are several promising areas for further research, such as the formation of the concept of effective CB with a scalable business model, the development of banking in the digital environment, analysis of the prospects for the interaction of CBs with Asian markets, the study of the investment banking capabilities.

These studies should concern such aspects of functioning of the banking system as the corporate and social responsibility of bankers and analysts of the domestic financial sector. As for the classical banking, then regardless of our preferences, it will wither away, and, accordingly, greater attention should be paid to developing of the electronic sphere with its rapidly evolving innovative filling.

But above all, it is necessary to solve the conceptual and methodological issues of whether to ensure resolution of all questionable financial market players, or to justify the creation of the system with 10-15 largest national banks in Russia with an extensive branch network and regulatory capital adequacy. The potential candidates for this narrow circle are, without a doubt, Sberbank, VTB, Alfa-Bank, Rosselkhozbank, VEB, and the whole range of the Gazprom financial structures, etc.

Abstract

This article explores the problem of unequal distribution of wealth between the interior and coastal regions in Tunisia. In this study, we provide the following methodology and tools to analyse regional disparities. We, first, develop a composite index of socio-economic development of delegations; this index is the result of a multidimensional scaling process of delegations according to their socioeconomic development's level; we, then, use two approaches to classify delegations in order to identify relatively homogeneous groups. The first approach is the discretization of the CISEDD index, and the second one is the classification of delegations according to the components of the CISED index. The results show, first, that the 24 governorates of the country are all concerned, although to different degrees, by deterioration of the socioeconomic conditions; second, socioeconomic status of the governorates of the country's interior is penalized relative to the costal governorates.

Keywords: regional disparities, composite index, regional development, Tunisia.

Introduction

Regional imbalances as those between rural and urban areas are, in Tunisia, the fruit of the historical heritage relationship between city and countryside, and even between regions, but they are also the results of the policies and development's choices made since the independence (Elloumi, 2006). The regional development's concept in Tunisia appeared after the independence. However, regional disparities persist or even increase, especially between cities and regions of Tunisia. Regional disparities in terms of amenities of life, sociodemographic and economic environment and employment, have continued to grow. Many rural areas have been the victims of a vicious circle combination, undeveloped infrastructure, low level of attractiveness and poor education. This explains the persistent gap between the regions of the interior and those in the coastal. Many factors have contributed to expand the gap between regions in Tunisia; The delay of the rural world is still high and the pressure on natural resources increase, it reflects the low degree to diversify the local economy and the inability of agriculture to ensure alone the rural development (Elloumi, 2006). The fact that the level of investment is against the agricultural sector explains that the predominantly agricultural areas are marginalized comparing to economically diversify areas. Also, the coastal regions are incurring extra costs such as pollution, congestion, and corruption. These costs affect the public budget and reduce the part of money allocated to the rural, which generates negative repercussions on the government's ability to develop interior regions.

After January 2011, regional development became the major concern of the Tunisian authorities. Tunisia must try to achieve a balance between coastal regions and those of the interior. The objective of regional development is not only to make a transfer from rich regions to poor regions to reduce regional inequalities, but to contribute to a dynamic growth and sustained regional convergence. The Government must allocate the budget development between regions according to a distribution key that aims for inclusive growth.

"The problem of unequal distribution of wealth, opportunities and economic activity continues to be an important and major problem in national and international level. Regional disparities are a feature

of the world, particularly of low and middle-income countries" (Fan and al, 2011). "As a rule, regional disparities take the shape of differences between the levels of incomes per capita and determine, at given moment, a chain reaction of companies, authorities, inhabitants, that attempt to counteract their escalation"(Antonescu, 2012). "The existence of regional disparities within a country remains an important theoretical and practical issue examined in planning and in allocation of resources and funds" (Goletsis and Chletsos□, 2011). The aim for regional policy is to reduce gradually the gap between the regions of the same country. So, the priority for many countries is the measurement of regional disparities and the identification of panelized regions.

The aim of the paper is, by the use of composite index of socio-economic development of delegations, to measure regional disparities, to emphasize the mechanisms governing socioeconomic inequalities and to make a new classification of delegations according to their level of development. In order to further examine the situation of socio-economic development delegations in Tunisia, we chose to design a composite indicator that incorporates a maximum of variables available by delegations.

The remaining of the paper is structured as follow: the first section presents a literature review on studies related to the measure of inequalities. The second section explains the methodological framework. It includes the framework for the selection indicator, structuring variables, the result of data structuring process through the principal component analysis and the last sub-section outlines the construction of our Composite Index of Socio-Economic Development of Delegations (CISEDD). Then, section 3 presents the socioeconomic classification of delegations and cartography of regional development in Tunisia. Finally, section 4 concludes the paper.

1. Studies Related to Measure Inequalities

Influencing factors cause the economic differences between regions. "The most known ones can be (mostly) historically structured creation of GDP in a region, natural conditions, settlement and demographic characteristics, linking with transportation infrastructure of international importance, volume of direct foreign investment and received grants" (Martinčík, 2008). Several studies have been conducted to measure inequalities between regions. The European Regional Policy used unemployment rate and GDP per capita. This statically indicators were much criticized (Grasland, 2004). The European Union authorities evaluate the development level of each region by using GDP per capita. The single indicator approach presents several limits, in order to provide the multidimensionality of human development; the notion of quality of life must be introduced (Goletsis and Chletsos□, 2011). The review of the literature reveals that the major studies by (Siriopoulos and Asteriou, 1998; Michelis and al, 2004) to analyze the Greek regions and their differences, focus on the statistics of GDP. Many research focused on multiple imperfections GDP / capita criterion Faced with the obvious limitations of such an indicator, some researchers have attempted to develop other tools to measure regional inequalities. For a new reading of regional disparities, several researches have proposed convergence as a measure of inter-regional disparities. Over the past decade, empirical studies on convergence have grown significantly and often present conflicting results. Siriopoulos and Asteriou (1998) have examined the regional convergence in Greece using the β-convergence tools and concluded that there was an economic dualism in Greece, in the sense that the northern and southern converge them, without convergence between the two groups. Tsionas (2002) has used data set different to that of Siriopoulos and Asteriou (1998). Furthermore the study confirms the economic dualism and non-convergence in Greece. Mauro-Podreca (1994) rejected convergence and found dualism between northern and southern Italian regions. Fan and al (2011) have used *Gini*, *Theil* and *Generalized Entropy* indices to measure China's regional disparities. An overview of these works concerning the measure of regional disparities can shows that the most of these studies are GDP based, without including other dimensions of development or quality of life. The need to find alternative measures to GDP has promoted the florescence of a whole battery of composite indicators (IC) in the early 90. United Nations Development Program (UNDP) has opened the floodgates of this new exploratory field with its Human Development Index (HDI) in 1990 (Dialga and Giang Le, 2014). The Human Development Index (HDI) represents the most applied and simple composite index to compare and make national measurement. "HDI has been introduced by United Nations as a composite index to aggregate three basic socio- economic dimensions of development and quality of life (longevity, educational attainment and standard of living/access to goods expressed as income)" (Goletsis and Chletsos, 2011). UNDP has developed three other composite indices, the index of

adjusted human development (IAHD), a measure that takes into account inequality in all three dimensions of the HDI by updating the average value of each dimension according to its level of inequality. Then the Gender Inequality Index (GII) that reflects the disadvantages of women in three dimensions: reproductive health, empowerment, and economic activity. The third one is the Multidimensional Poverty Index (MPI) that can identify deprivations in education, health and income; this index uses 10 indicators on three dimensions. By aggregating a set of welfare indicators, Ezzrari (2009) constructed a composite index of Living Standards in Morocco (LSI); this index is a multidimensional measure of living standards. It is precisely to remedy the inadequacies of the analytical dimensional monetary indicators (Ezzrari, 2009). To overcome the shortcoming of the GDP only based approaches, Goletsis and Chletsos (2011) incorporate the multi-dimensional notion of quality of life / well-being to develop a composite index to assess Greek regions and then, they applied multivariate clustering for identifying regions with similar socio-economic profiles. Many other composite index approaches can be found, Bobbitt and al (2005) proposed the Well-Being Index and Annoni and Kozovska (2010) defined the EU Regional Competitiveness Index. These authors had included economy, infrastructure, cohesion, education, labor market, environment, health, etc.…as dimensions to construct their specific index.

To measure regional development in Tunisia, the Ministry of Regional Development & Planning of Tunisia built a regional development index (IDR), which clearly showed regional disparities. This index is composed of 4 different indicators: index of "know", index of "wealth and employment", index of "health and population" and, index of "justice and equity".
Composite indicators are important tools of communication and analysis support systems to decision making because they synthesize the information in individual indicators. They allow comparison of the countries (regions, businesses, etc.) with respect to their performance in various fields.

2. Materials and Methods

2.1 Methodology

“Composite indicators are increasingly recognized as a useful tool for policy making and public communications in conveying information on countries’ performance in fields such as environment, economy, society, or technological development” (Nardo and al 2005). According to (the Center for Demographic Studies and Research of Morroco **[**CDSRE**],** 1999), recent years have been marked by the development of new composite indices of development used as criteria for the classification of countries, regions, communities and local governments based on human development. The importance of these indices inform about combined deficiencies in resources, income, longevity, quality of life and access to factors of sustainable self-protection against the various deprivations. These indicators often synthesize economic criteria and socio-demographic parameters. Given the importance of these indicators, the effectiveness of a development strategy depends on living conditions and educational and professional skills generated by the process of economic growth and investment in human capacity; fundamental guarantees of the perpetuation of wealth creation and maintaining growth rates at sufficient levels.

Valued as it is done so far in Tunisia, the average points of different governorates, socio-economic indicators can certainly appreciate the level of development at the regional level but it remains analytically limited given the strong dispersion of the spatial and social distribution of circulating levels of social and economic prerequisites for development within the same governorate. The items included in the calculation of these indicators are thus subject to strong variations between the delegations of the same governorate so that their averages are subject to high dispersion and therefore statistically limited. A direct appeal to the variables used in calculating such indicators and their differentiation level delegations, are the most appropriate statistical approach to the identification of the most deficient social and economic fields and the most excluded populations from development. As they are identified by the UNDP, the composite indicators of development are limited to literacy, education, average income levels, differentiated participation of women in the creation of national wealth, socio-professional status, nutrition of "less than 5 years", and access to drinking water and

sanitation services. They are therefore inadequate as a representation of all socio-economic conditions in the delegations.

It is in this light that we wanted to complete the list of indicators on consumption, housing conditions, employment, unemployment, underemployment and access to physical and social infrastructure (electricity, paved roads, schools, clinics…), the factors of production, and financial resources. Production patterns and the incidence of poverty also fall among selected indicators.
To clarify the situation of socio-economic development of delegations, we used Principal Component Analysis (PCA) as an intermediate step prior to calculating the emergence of new synthetic variables (latent), which will be retained for the sake of parsimony as variables relay to initial variables. Multidimensional scaling techniques (MDS) are then applied to factors to establish a Composite Index of Socio-Economic Development of Delegations (CISEDD) in Tunisia.

2.2 Indicator selection

The selection of indicators reflecting the degree of socio-economic development is all the more justified it refers to a precise concept of development (CDSRE, 1999). Based on the theory to construct a tool able to capture different development dimensions and to cover both economic and social aspect, we distinguish three main pillars: the first one is related to the amenities of life indicating the existence of acceptable living conditions of citizens of each regions. Social level, potential of human capital, demographic pressure and demographic growth are factors related to the second pillar the sociodemographic environment and the third one is interested to the economic environment and employment which include four factors: the level of labor market's absorption capacity, the tensions on the labor market, the notions of economic activities' diversity and the business' scope. The set of indicators, which populate each pillar, is carefully chosen according to the literature review, and data availability. According to (Bobbit et al 2005) the list of potential indicators, which identified based on the literature should apply on a set of criteria.
- Contribute logically to the index concept.
- Be understandable and interpretable by the general public.
- Not be identified as a poor indicator by theory.
- Have regional data available now and in the future (so as to provide a tool for future comparisons).
- Come from credible sources.
- Have the same measurement methodology across regions and over time/years.
- Show variability and frequency adequate to be reflective of regional change.

At the end of this stage, we were able to recover 31 indicators measuring the level of diffusion of various aspects of socio-economic development in Tunisian delegations[1]. The final index is composed of a total number of eleven indicators, chosen by a starting set of 31 candidate indicators (see annex I). For easier reading of the various selected indicators, we agreed to combine variables into four categories, each referring to one aspect of regional development in the delegations:

1. Amenities of life.
2. Socio-demographic environment.
3. Economic environment and employment.

2.3 Structuring variables

The main goal of our approach is to find an overall underlying logical data, which ensures the validity, the relevance and importance of the selected indicators to account for the situation of socio-economic development delegations. A series of Principal Component Analysis (PCA) was then applied at each field in order to:

- Summarize the information contained in the database established for this purpose.
- Study the redundancy between some indicators.
- Purify the list of indicators by discarding those that provide only marginal information.
- Identify from indicators a smaller number of dimensions or factors that are responsible for the preparation of conceptual framework of the index.

➢ Serve as an intermediate stage prior to calculation of the use of classification methods, multidimensional positioning and calculation of scores.

In the following paragraph, we review the results of structuring original variables in each field using the PCA. The results of each analysis are grouped into a single summary table, which shows the name of the selected initial variables, and the manner in which they are structured around dimensions (principal components) extracted according to the previous approach. The implementation of the PCA was performed using the procedure of SPSS Factor Analysis.

Before applying the method we will focus on the analysis of variables taken into consideration to see if we can apply the method of main component analysis (Pintilescu, 2007). "The Kaiser-Mazer-Olkin (KMO) and Barlett tests also help us to see whether between variables there is a statistical correlation or not. The null hypothesis implies the independence hypothesis while the alternative hypothesis implies the dependence between variables" (Chirila, V and Chirila, C; 2014).

2.4 Results of variables structuring

2.4.1 Results of variables structuring attached to the first category: "amenities of life"

Table 1 shows that the 10 selected indicators at the first category "amenities of life" can be grouped under three dimensions.

1. The first dimension related to "*the levels of infrastructure's development and the diffusion of basic equipment facilities in the delegations*". It includes variables: "*Distance from the poles: Tunis, Sousse and Sfax*", "*Average distance access to airport and port services*", "*Part of classified roads*", " *Connection rate to wastewater system*" and " *Connection rate to drinking water*", with an inertia rate or restored information, on the order of 31.091%.
2. The second dimension includes 3 variables: "*Number of doctors per 1000 inhabitants*", " *Number of beds per 1000 inhabitants*", and "*Number of pharmacies per 1000 inhabitants*" with inertial restored rate on the order of 18,733%. It reflects *the medical density or level of access to care in delegations*.
3. A third dimension, which refers to *levels of availability and distribution of leisure centres in delegations*: it restores 16.115% of the initial information and includes two variables: " *Number of leisure centres per 1000 inhabitants*" and "*Diversity of leisure centres*".

Table 1: factorial structure associated to indicators related to category I: "Amenities of life"

	Infrastructure and basic equipment	Health	Leisure
Restored information:	Eigenvalue 1	Eigenvalue 2	Eigenvalue 3
65,939%	3,109 (31,091%)	1.873 (18,733%)	1,612 (16,115%)
Distance from the poles: Tunis, Sousse and Sfax	-,895 (0,816)		
Average distance access to airport and port services	-,889 (0,809)		
Part of classified roads	,682 (0,676)		
Connection rate to wastewater system	,656 (0,530)		
Connection rate to drinking water	,624 (0,678)		
Number of doctors per 1000 inhabitants		,741 (0,561)	

Number of beds per 1000 inhabitants	,676 (0,514)
Number of pharmacies per 1000 inhabitants	,616 (0,542)
Number of leisure centres per 1000 inhabitants	-,845 (0,769)
Diversity of leisure centres	,709 (0,699)
KMO: 0,738 – Bartlett test: CHI SQUARE: 1127, 145 ; DF : 45; sig :0,000…	

2.4.2 Results of variables structuring attached to the second category: "Socio-demographic Environment "

Table 2 refers to the factorial structure after the PCA's application on 11 variables used to understand the socio-demographic environment in delegations. This table shows that:

1. The variables: "Poverty rate", "Illiteracy rate", "Dependency rate of the population" and "Number of Needy Families", are grouped around the first dimension with an inertial restored rate to about 25.309% to put in evidence *the social level* in delegations.
2. The second dimension, with an inertial restored rate in the order of 23.492%, is reserved for the *potential of human capital* in the delegations resulting grouping variables: "*Part of educated inhabitants*", "*Average number of students per class in basic education*" and "*Average number of pupils per teacher in secondary education*".
3. The variables related to demographic characteristics of the populations of the different delegations have monopolized alone last two dimensions. These are from two different registers: the first referring to two variables: "*Population density per km2*" and "*Polarization of the population's age structure*" is concerned by *demographic pressure* in delegations. The second focuses on *the demographic growth* in delegations as references variables: "*Net migration*" and " *Annual average growth rate of the population*". The inertial restored rates by these two dimensions are respectively in the order of 18.403% and 15.217%.

Table 2: factorial structure associated to indicators related to category II: "Socio-demographic Environment "

	The social level	Potential of human capital	Demographic pressure	Demographic growth
Restored information: 82,421%	Eigenvalue 1 2,437 (25,309%)	Eigenvalue 2 2,262 (23.492%)	Eigenvalue 3 1,772 (18,403%)	Eigenvalue 4 1,465 (15,217%)
Poverty rate	,936 (0,876)			
Illiteracy rate	,802 (0,834)			
Dependency rate of the population	,694 (0,832)			
Number of Needy Families	,672 (0,621)			
Part of educated inhabitants		,834 (0,734)		
Average number of students per class in basic education		,778 (0,612)		
Average number of pupils per teacher in secondary		,634 (0,567)		

education	
Population density per km2	,812 (0,775)
Polarization of the population's age structure	,743 (0,783)
Net migration	,847 (0,720)
Annual average growth rate of the population	,832 (0,758)
	KMO: 0,741 – Bartlett test: CHI SQUARE: 1087, 1402; DF: 28; sig :0,000…

2.4.3 Results of variables structuring attached to the third category: " Economic Environment and Employment "

The factorial structure resulting the PCA's application on 10 indicators related to the economic environment and employment, is summarized in Table 3. It shows four dimensions. The first and fourth seem to be associate to realize the situation of the labour market in delegations. The two others refer to economic environment.

1. The first dimension represents with an inertial restored rate 21,464%, *the level of labor market's absorption capacity* of the delegation which includes: "*Number of job offers per 1000 inhabitants", "Investment's rate" and "Number of firms per 1000 inhabitants*".
2. With the lowest inertia rate (about 12.556%), the fourth dimension associates variables: "*Unemployment rate*" and "*Number of job application per 1000 inhabitants*". It presents *the tensions on the labor market* in delegations.
3. With the same inertia restored rate (18.258% and 18.003%, respectively), the second and third dimension respectively suggest *the notions of economic activities' diversity* and *the business' scope* in the delegations. The first concept refers to the variables "*Polarization sector of the labour force*", "*Specificity of the activity structure of the labour force*" and "*Index of economic concentration*". While the second focuses on the variables "*Average size of the private sector's firms*" and "*Part of employment in the private sector's firms*"

Table 3: factorial structure associated to indicators related to category III: "Economic Environment and Employment"

	The level of labour market's absorption capacity	The notions of economic activities' diversity	The business' scope	The tensions on the labor market
Restored information: 70,281%	Eigenvalue 1 2,146 (22,464%)	Eigenvalue 2 1,862 (18,258%)	Eigenvalue 3 1,800(18,003%)	Eigenvalue 4 1,256 (12,556%)
Number of job offers per 1000 inhabitants	,872 (0,833)			
Investment's rate	,819 (0,741)			
Number of firms per 1000 inhabitants	,725 (0,674)			
Polarization sector of the labor force		,749 (0,725)		

Specificity of the activity structure of the labor force	,689 (0,576)		
Index of economic concentration	,662 (0,493)		
Average size of the private sector's firms		,828 (0,827)	
Part of employment in the private sector's firms		,790 (0,790)	
Unemployment rate		,	,827 (0,763)
Number of job application per 1000 inhabitants			,621 (0,763)
	KMO:– Bartlett test: CHI SQUARE:; DF: sig : …		

Figure 1 summarizes the results of previous Main Component Analysis and shows the structure of the index proposed by domain and subdomain development that follows.

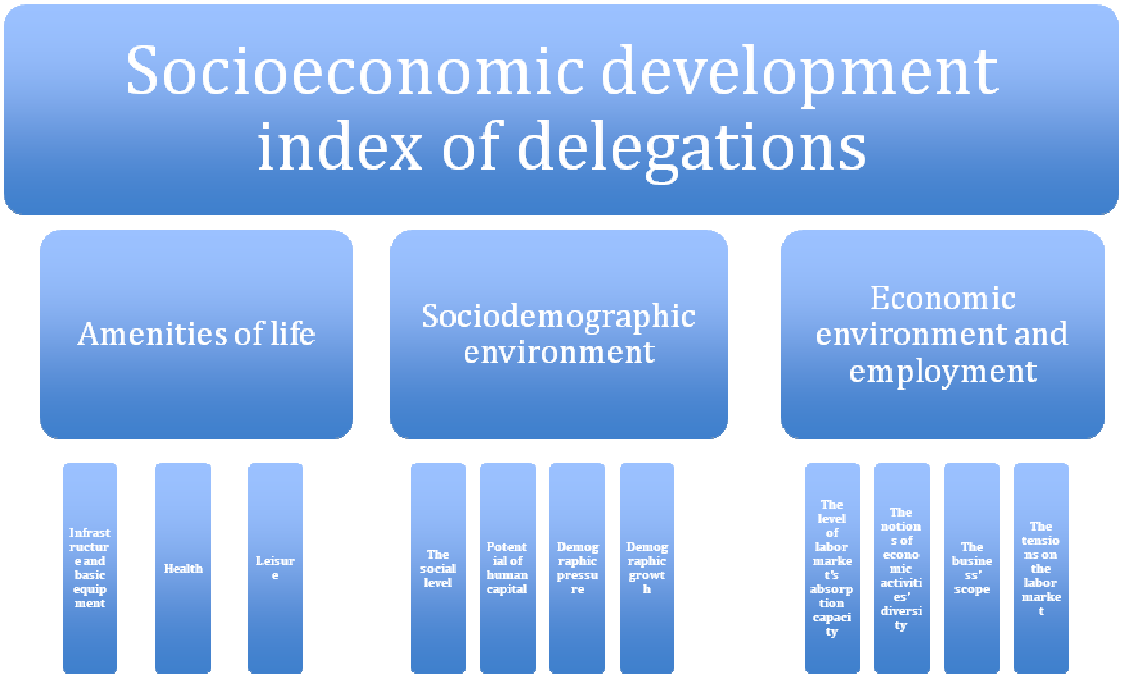

Figure 1: Areas covered by the index

Socioeconomic development's factors of delegations, resulting ACP lead to various uses. For our part, we opted for a multi-level approach seeking to develop a complete statistical and unified portrait of all Tunisian delegations in socio-economic development. Thus, a Composite Index of Socioeconomic Development of Delegations (CISEDD) will be established to account for regional disparities, take note of the socioeconomic mechanisms governing these inequalities and precede at the same time a revision of the regional priorities' map in Tunisia. Then, "Multi-Dimensional Scaling" method (MDS) is applied to factors to establish a Composite Index of Socioeconomic Development of Delegations (CISEDD).

2.5 Composite Index of Socioeconomic Development of Delegations (CISEDD).

The proposed index is the result of a multidimensional scaling (MDS) process of delegations according to their level of socioeconomic development. « Multidimensional scaling, in its most basic formulation, sets out to represents a set of objects in a low-dimensionality space" (Arce and al, 2010). « For given set of proximities, MDS attempts to find a set of points such that distances (d_{ij}) between those points correspond as closely as possible to these proximities" (Ahmed and Miller, 2007). This involves solving the following function.

$$Mm\ \{dij\}\sigma = \sum (dij - f(\delta ij))2$$

Where f( ) is an hypothesized proximity function.
We relied on Multidimensional Scaling to develop spatial maps to visualize the form of positioning points (delegations) in a space metric (Euclidean) having a number of dimensions as small as possible (principle of parsimony) with maximum of fidelity (measured by the existence of a monotonic relationship between the results and the initial data). « The number of dimensions, usually small (two, three, four), is decided by the researcher for substantive reasons, through it can also be set on the Basis of statistical criteria" (Arce and al, 2010).

In the MDS literature, there are different methods allowing us to calculate the index, the applications in this paper use the PROXimity SCALing (PROXSCAL) technique (Commandeur and Heiser, 1993) implemented in SPSS. PROXSCAL is a recent technique that implements the Iterative Majorization (IM) algorithm (Commandeur and Heiser, 1993). Two references points are incorporated into the analysis. The first is an ideal point, which arises from a "perfect" combination of socioeconomic characteristics, responding as close as possible to an ideal development situation. Conversely, the second is considered an anti-ideal point, which represents an extreme situation of socioeconomic deprivation.

Table 4: Ideal and anti-ideal point's characteristics

Sociodemographic factors	Ideal point	Anti-ideal point
Infrastructure and basic equipment	The minimum sample value	The maximum sample value
Health services	The minimum sample value	The maximum sample value
Leisure	The minimum sample value	The maximum sample value
Social level	The minimum sample value	The maximum sample value
Potential of human capital	The minimum sample value	The maximum sample value
Demographic pressure	The minimum sample value	The maximum sample value
Demographic growth	The minimum sample value	The maximum sample value
The level of labour market's absorption capacity	The minimum sample value	The maximum sample value
The notions of economic activities' diversity	The minimum sample value	The maximum sample value
The business' scope	The minimum sample value	The maximum sample value
The tensions on the labor market	The minimum sample value	The maximum sample value

From the point of view of the graphical representation, the concept of ideal point versus anti-ideal leads us to a space where a point indicates each delegation, and where all points are represented by a direction from the anti-ideal points (high socioeconomic deprivation situation) to an ideal point (high socioeconomic promoting situation). In this representation model, called "point-vector model" is the order of the projections (orthogonal) to the direction of the points representing the delegations in space, which should reflect the order of socio-economic development of the Tunisian delegations. (Figure 2) corresponds to the socio-economic development's map of delegations, that it has been recovered from MDS analysis. The purpose of the multidimensional-scaling analyses is to obtain perceptual maps corresponding to the input data, with the smallest possible number of dimensions. The cards are made such that the adequacy is improved when the number of dimensions increases, hence the necessity for compromise. The adequacy of a solution is usually evaluated from the measurement of stress; large stress values indicate low adequacy. "Generally, lower dimensional solutions have higher stress. Increasing dimensionality improves the goodness-of -fit, however, at a certain point raising dimensionality does not decrease stress substantially. This is most appropriate dimensionality and the configuration at this dimensionality is the solution" (Ahmed and Miller, 2007). The number of dimensions is determined by applying the elbow criterion. The rule is that; a value ≤ 0.1 represents the best dimension and it's not tolerable to check a value ≥ 0.15 (Kruskal & Wish, 1978). "There are two types of indicator: those for which zero represents a perfect fit (of this first type would be the indicators Normalized Raw Stress); and those for which the perfect fit is represents by 1(of this second type would be Dispersion Accounted For and Trucker's congruence coefficient)" (Arce and al, 2010).

Thus, a graphic representation of the stress based on the number of dimensions can be instructive. The set of points usually gives a convex shape (see Figure 3). The point where the elbow is formed indicates the appropriate number of dimensions. Beyond that, the adequacy does not improve substantially. In our case, the criterion of the elbow seems to favour a solution in three dimensions with a normalized raw stress value 0.0251 order, value that corresponds to a high quality adjustment according to the Kruskal scale which is most commonly used to test the lack of adequacy. The relevance of a three-dimensional solution is also attested by the value of 0.987 (very close to one) that it has been recorded for the index of congruence of Tucker.

Table 5: Goodness-of-fit indices offered by PROXSCAL

Normalized Raw Stress	0.0251
Trucker's Congruence Coefficient	0.987

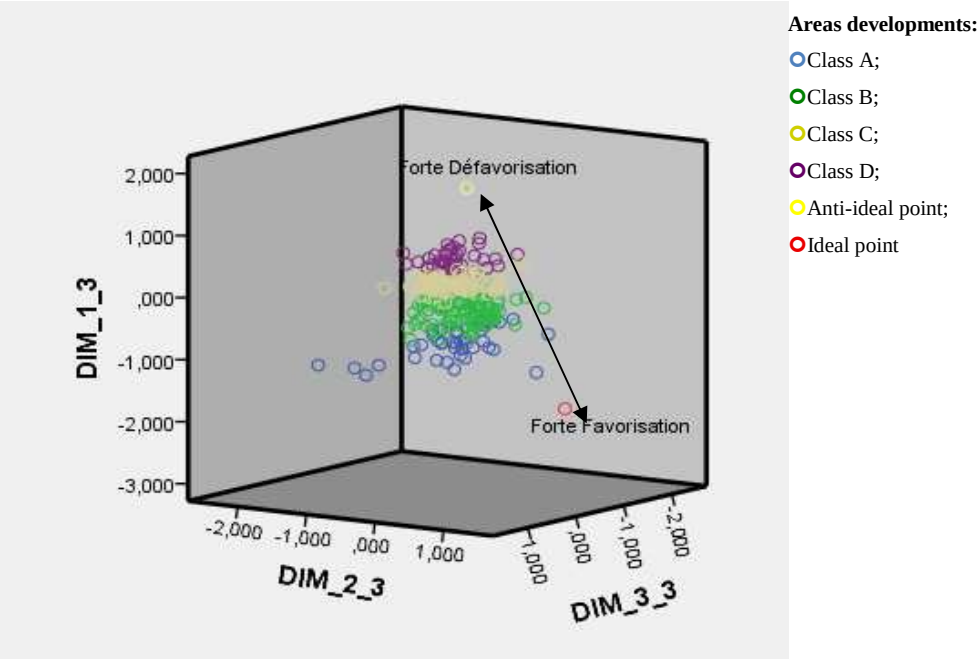

Figure 2: Socio-economic development's map of delegations

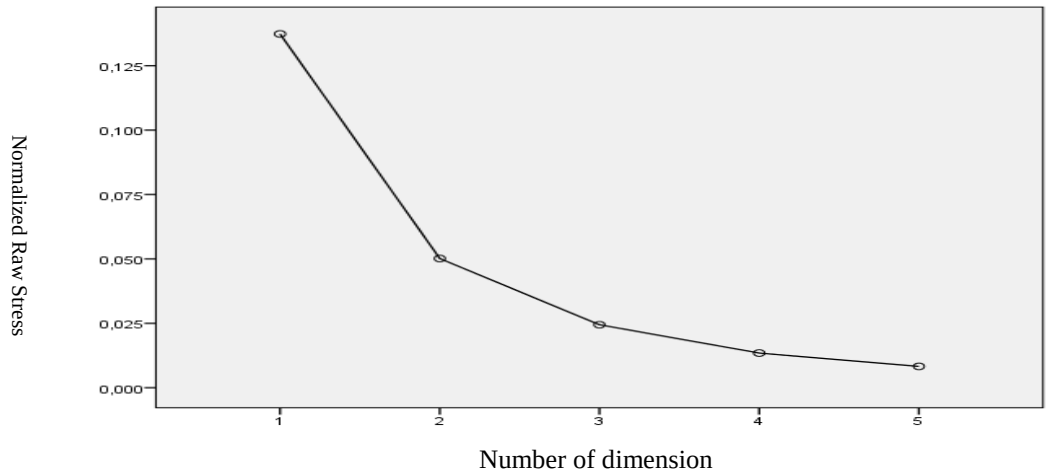

Figure 3: Scree plot's graph

From this card, we have established a multidimensional scaling of delegations in an order that ranges from the most deprivation situations to the most promoting situations on socioeconomic development. For each point, the ratio between the two distances that separate the ideal point on the one hand, and anti-ideal point on the other hand, can be used as an indicative criterion of the level of socio-economic development of the corresponding delegation. The values thus calculated are used to form a new Composite Index of Socioeconomic Development of Delegations (CISEDD):

$$CISEDD = ln\left(\frac{d^2(P_D, P_I)}{d^2(P_D, P_{AI})}\right)$$

Where : P_D, Point-Delegation ; P_I, Idéal point; $P_{A\text{-}I}$, Anti-Idéal point; d, Euclidean Distance ; ln, Natural Logarithm

A positive index value (negative respectively) indicates a promoting socioeconomic situation (respectively, deprivation socioeconomic situation). This index has the advantage of being relatively easy to interpret and it allows characterizing the delegations for their development's level.

2.5.1 Preliminary index results

On the card (Figure 2) we can see that there is a strong presence of points on the side of anti-ideal point. This trend indicating a situation of socioeconomic deprivation widespread among delegations resulted in a very large proportion of negative values in the index. This part around 96%is also materialized by negatives values that were recorded for all central position indices, including the average and the median index (table 6). These results confirm the hypothesis of normality of the distribution of the index. At this level, the Kolmogorov-Smirnov and Shapiro-Wilk tests are unambiguous. From (Table 7), the normality hypothesis is retained in both cases with significance levels in the order of 0.176 and 0.315, respectively.

Table 6*:* Descriptive statistics of CISEDD

		Statistics	Standard Error
Average		-,5384	,01933
Confidence interval 95% for the average	lower bound	-,5765	
	upper bound	-,5003	
Truncated mean on 5%		-,5372	
Median		-,5261	
Variance		,099	
Standard deviation		,31413	
Minimum		-1,35	
Maximum		,21	
Interval		1,56

CISEDD	,052	264	,176	,994	264	,315

The "box plots graph" is prepared essentially to understand the disparities within and between governorates in socio-economic development. It also seems to support this rather disturbing of socioeconomic deprivation of the majority of delegations of countries. This type of graph is used to display the main specifications of a given distribution and facilitates comparison of distributions using quartiles. The upper and lower sides of each rectangle represent the first and third quartile, respectively; inside trait represents the median. A box length represents the central part of the distribution, which is the interquartile range. “Whiskers” corresponding to adjacent values complete the box:

- Upper adjacent: larger value lower than Q3 + 1.5 (Q3-Q1);
- Lower adjacent: smaller value upper than Q1 - 1.5 (Q3-Q1).

The outside points represent extreme values.
Indeed, negatives values recorded at the median of the 24 governorates of the country; show that they are all concerned, although to different degrees, by deterioration of the socioeconomic conditions. In order to further analysis, we established a ranking of governorates according to their level of socioeconomic development. At (Figure 4), they are arranged on the x-axis from left to right in ascending order of the level of socioeconomic development. Again, another trend emerges; socioeconomic status of the governorates of the country's interior is penalized relative to the coastal governorates. Indeed, they are the only ones, except the Governorate of Mahdia, held positions above the median level of socioeconomic development recorded for all delegations in the country. Similarly, we can see also that it is only in the governorates of Tunis, Ben Arous, Ariana, Monastir, Sousse and Sfax, all also located on the coast, where we could identify some delegations with a positive score meaning a very favoured position compared to other delegations.

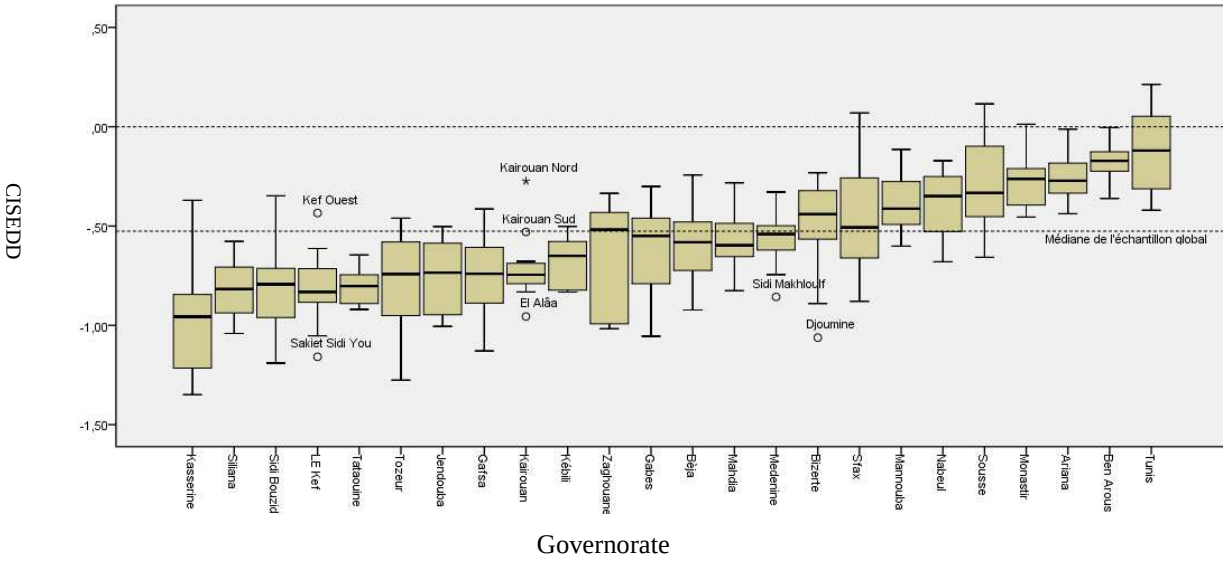

Figure 4: Box plots graph

To illustrate the spatial structure of socioeconomic disparities of development between the coastal governorates and those inside the country, we developed a mapping index CISEDD through thematic maps. In terms of presentation, we selected for each of the two regions a choropleth map of the index’s mean at the governorate level (this is the arithmetic mean of the index recorded for the delegations of the same governorate). The categorization of governorates in relation to their average level of socioeconomic development is expressed by colour ranges given on a scale of six dyed graduated, (from the darkest to the highest in more clear values for the lowest values of the index). For comparison purposes, the limits of the classes are represented in the two regions on the same scale at the bottom of (Figure 5).

The dual character of socio-economic development between the coastal areas and those in the interior of the country is so certified by the difference in dyed colour between the two cards. At this level, the

costal governorates mark their superiority over those of interior by dark colour. For their part, clear dyed meaning their penalization in socio-economic development marked the governorates of the interior

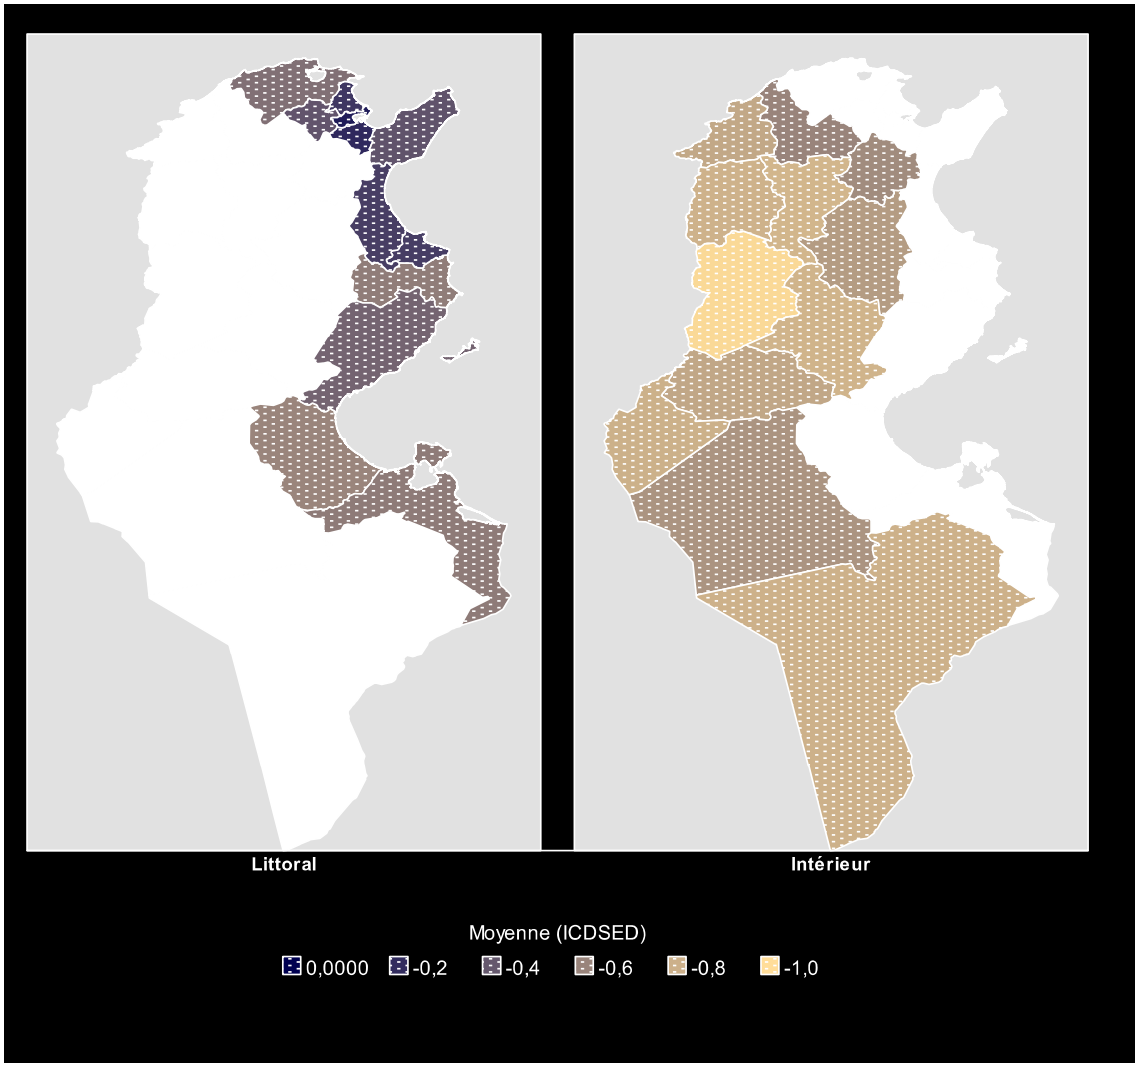

Figure 5: Index's map

The index also suggests disparities related to the degree of urbanization of the delegations. Indeed, according to the "Box Plots graph" (Figure 6), we concluded that in Tunisia rural means underdevelopment, although some sections of the population in urban environment also seem not to be spared the degradation of socioeconomic conditions.

All these results suggest the possibility of a process to reproduce a hierarchical structure of socio-economic development among the delegations and reinforce a certain dualism. Spatial disparities allow opposing an advantage segment (the capital and the coast) and a disadvantage segment (inside), while those on the "middle" point to the favoring (or deprivation) urban areas (rural). Urban concentration was made on the coast (from Bizerte to Gabes), which includes 76% of the urban population. This urbanization was a strategy of deliberate policy, which accentuated regional inequalities.

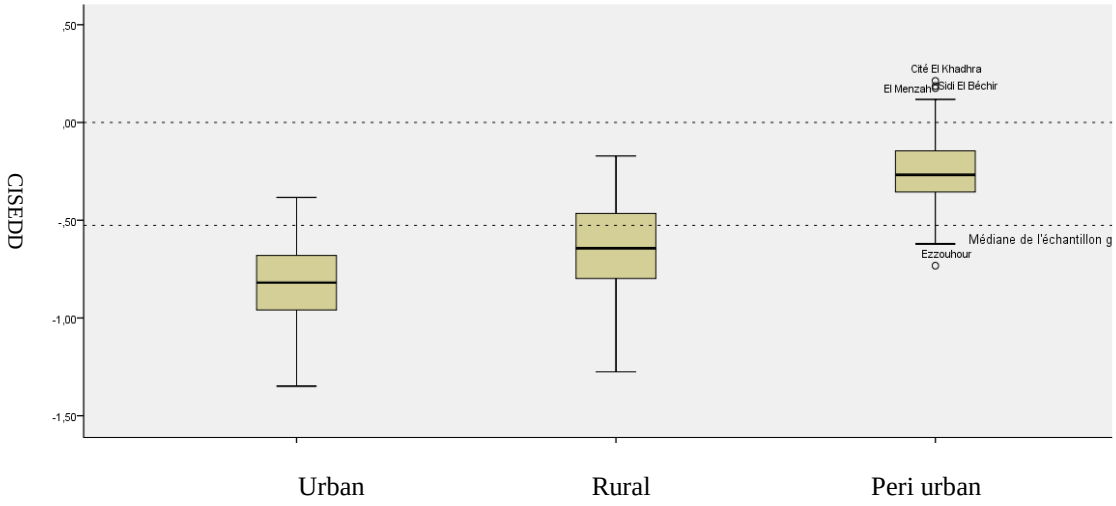

Figure 6: Box plots graph

2.5.2 The importance and reliability of CISEDD Index

The purpose of this section focuses on the quality of CISEDD index. From this point of view, the CISEDD index must establish a correspondence between a theoretical level (conceptual definition of socio-economic development of delegations) and an empirical level (definition of indicators used occasionally and which is based on the calculation of the index). Indeed, as calculated, the CISEDD index is implicitly associated with a multidimensional view of the development' concept, a view that falls within complex and inextricable relationship between various components: demographic, social and economic. In terms of construction, the aggregation of all these components is made to the means of factor analysis and multidimensional scaling techniques.

Reflections initially conducted on the process of determining the index and the fundamental properties of the results are here supplemented by analysis of validity (content) and reliability (internal consistency) of the index. This, has led us to raise two important questions:

1) What aspects of the delegation are taken into account?
2) Factors are they consistent in the index's composition?

In this perspective, we used a multiple regression model expressing the CISEDD Index, based on factors to take note of the importance and the way in which the various development indicators involved in the index's formulation.

The results of the model estimated by **ordinary least squares method** are given in Tables 8.1, 8.2, 8.3 (see annexes). These results relate to the best specification that can be retained to study the index's composition. In terms of approach, this specification is the result of an automatic learning process applying the principle of selection "ascendant step by step" for the explanatory variables in order to a better model performance. This is also evidenced by the very value close to one (0.96) of the adjusted R-squared (see Table 8.2). Fisher's test is concluding and indicates that the model is globally significant (see Table8.1). From Table 8.3, the eleven factors appear to be involved in the expected direction (sign of regression coefficients) and significantly (level lower than 0.05) in the composition of the index. A careful reading of the fourth column of the same table is used to establish a ranking. Regarding the factors, the economic indicator for the size of companies operating in the delegation that holds the upper hand, followed by the indicators of infrastructure, leisure and social level. The indicators related to the diversity of economic activities, the absorption capacity of the labour market and the potential of human capital appear to be the third level and anticipate in the same time the indicators related to health services and tensions of the job market. Occupying the last two positions, both indicators on the demographic situation in the delegations are like most penalized

at the end of this ranking. In total, eleven components were found relevant in the construction of the index and seem mostly be very consistent evidence in order to establish a sufficiently differentiated portrait of delegations in socio-economic development.

3. Socioeconomic Classification of Delegations and Cartography of Regional Development in Tunisia

To extend the analysis, we performed a classification of delegations in order to identify relatively homogeneous groups, thus generating socio-economic profiles on the basis of eleven factors from ACP as the influence that they exert on the CISEDD index. To do this, factor analysis of Correspondences (FAC) has been initiated in order to reconcile between two approaches used to determine the groups: the discretization of the CISEDD index and cluster analysis from eleven factors from ACP.

3.1 The classification of delegations from the class's discretization of the CISEDD index

In order to draw up a map of regional development in Tunisia, a first classification of delegations is established on the basis of a class discretization of CISEDD index. The normality of the distribution of index values gave us the right to apply the standardization technique as an approach to thresholding. The standardization is to define a first class centred on the mean and a magnitude of a value of standard deviation. The other classes are then incremented by one step to the value of one standard deviation on either side of this central class. Under these conditions, each class is determined by a fractional standard deviation relative to the average. This discretization technique named standardized classes method according to average and standard deviation has the major advantage to establish classes that rely on threshold of statistical significance rather than arbitrary arithmetic (quantile method, equal thresholds range). Figure 7 shows the distribution of the delegations at the frequency of belonging to different classes that have been recovered from the discretization of the index. This is a unimodal distribution characterized by a high concentration of the delegations at the two central classes adjacent to the average. The frequency of the delegations in the class's decreases fairly symmetrical and gradually as the distance from either side of the average. Thus, we quantified 5 delegations recorded a score higher than the threshold of 1.1 to form the group of the most socio-economically advantaged delegations in the country. These are the delegations of Tunis Bab Bhar... In contrast, the seven delegations ... having recorded a score less than -1.17 are grouped together to designate the poorest socio-economically class of delegations.

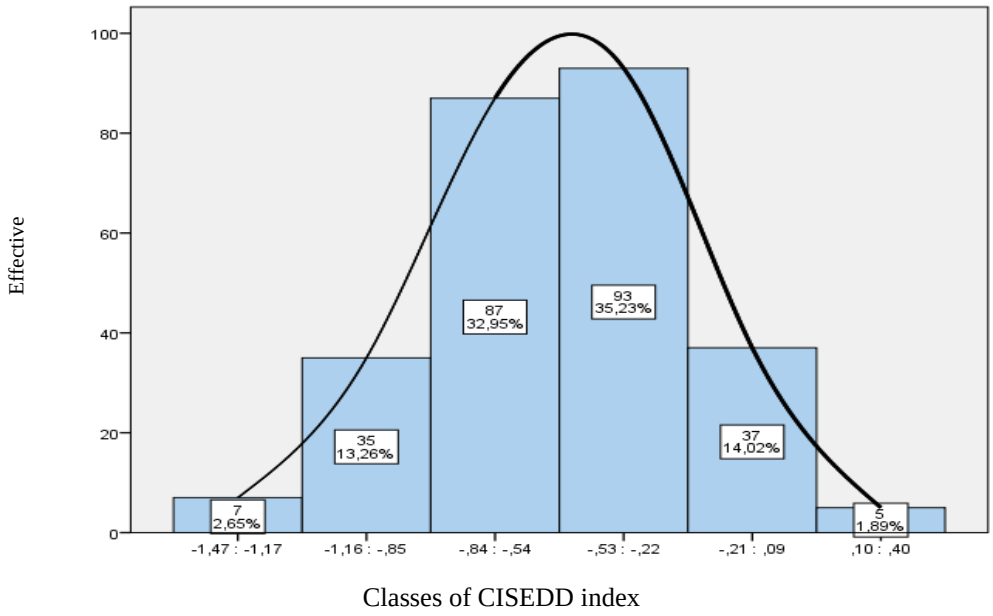

Figure 7. The distribution of the delegations from the discretization of the index

3.2 The classification of delegations according to the components of the CISEDD index

The determination of groups is performed on the basis of a process of hybrid cluster analysis combining hierarchical and non-hierarchical classification methods. More precisely, it is a cluster analysis in two steps. In terms of "stricto sensu method", it is to make an initial classification of delegations by a process of hierarchical ascending classification as a method of partitioning. And a classification is carried out by the mobile centers or k means. Thereby obtaining final classes, which are assigned the initial observations by means of their pre-classes from the first step (the classes centres provenent from hierarchical classification process are retained as the initial solution to start the process of non-hierarchical classification). The hierarchical process is called ascending if it begins with objects (individuals) to form classes, and said descendant if it begins with the set and selected partition that maximizes the ratio between intergroup variance and total variance. After, it comes to choosing the number of classes in arbitrating with the degree of heterogeneity in groups. On the graph, it is indicated by a scale from zero (level of extreme homogeneity) to twenty-five (level of extreme heterogeneity). This tree (figure 8) shows that a partition to four groups seems to be more appropriate to account for socio-economic development disparities between the delegations (see annexes).

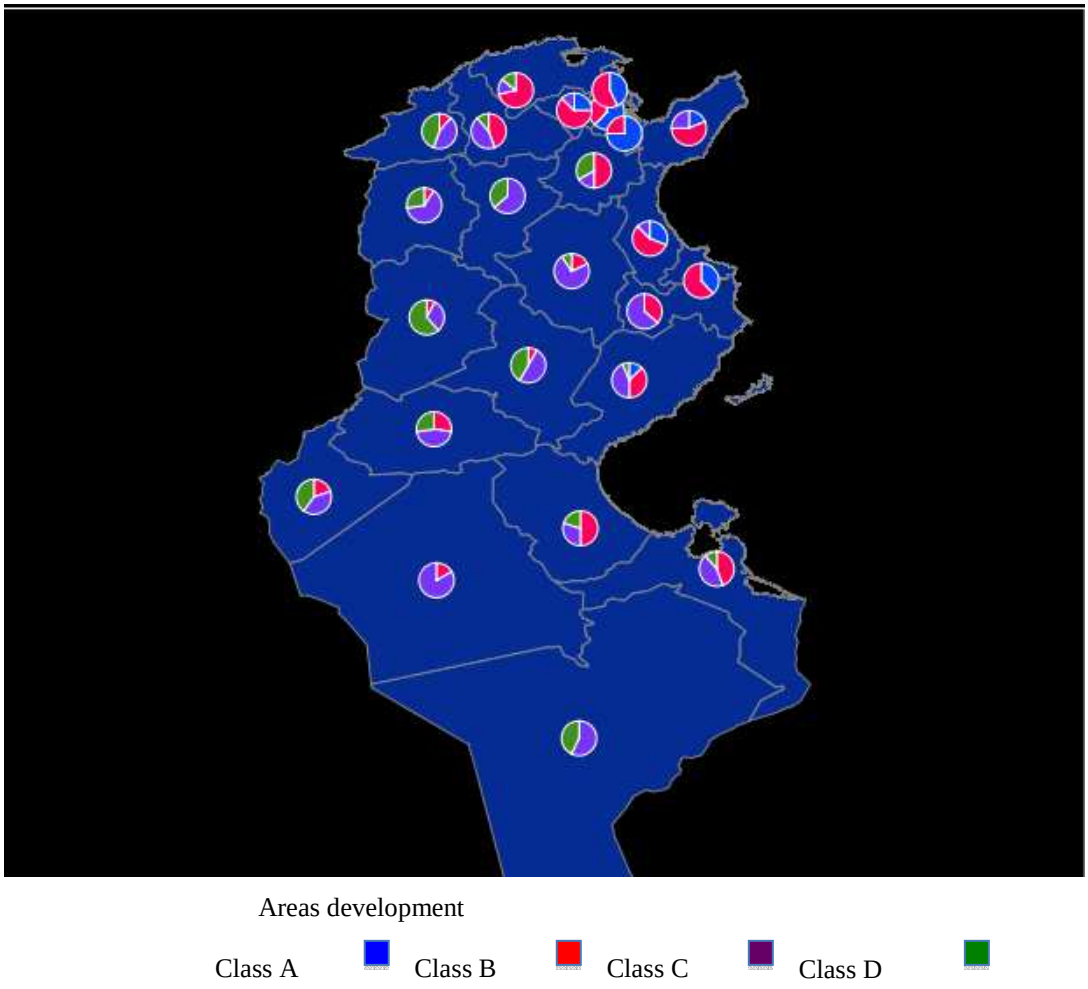

Figure 9: The regional development map by governorate in Tunisia
Distribution of delegations by development's classes

4. Conclusion

This paper supports the hypothesis that the disparities between the regions of coastal and those of the interior are very important in Tunisia. Our research has allowed us to make a classification of the delegations using our composite index (CISEDD), which is the result of a multidimensional scaling process of delegation according to their socioeconomic development's level. Our results show that the 24 governorates are all concerned, although to different degrees, by deterioration of the socioeconomic conditions. Also, the governorates of the interior are penalized compared to costal ones. Except the governorate of Mahdia, the governorates of Tunis, Ben Arous, Ariana, Monastir, Sousse and Sfax benefit a favorite situation compered to other delegations of the interior. And to push our research further, we investigate the consistent of the factors in the index's composition. In this perspective, we used a multiple regression model expressing the CISEDD index based on factors to take note of the importance of indicators in the index's formulation. The eleven factors appear to be involved in the expected direction and significantly in the composition of the index. We conclude that the economic indicator "firm scope" is the most important factor in index's composition. And to extend the analysis, we performed classification of delegations in order to identify relatively homogenous groups, our results show that a partition to four groups seems to be more appropriate to account for socio-economic development disparities between the delegations. This classification has still allowed us to show that coastal regions are ahead of the inland regions.
The results of this paper represent a contribution to the debate of regional development, and the gap of development, which persist between delegations in Tunisia.

Annexes

Table: Socio economic development's indicators of the delegations	
Category I: Amenities of life	
Distance from the poles: Tunis, Sousse and Sfax	The kilometre distance between the delegations of big cities of Tunisia (Tunis for the North, Sousse for the centre and Sfax for the South). It reflects, in some way, the geographical proximity of each delegation poles of economic activity
Average distance access to airport and port services	Kilometre distance from each delegation from the nearest pole (port, airport). It allows us to appreciate the ease of business transactions including each delegation with the outside
Connection rate to wastewater system	The housing proportion connected to the sewerage system of ONAS in the delegation. It reflects the quality of life.
Part of classified roads	The ratio of classified roads in Kms on total of roads in each delegation. It includes the road network consists of highway, regional road and local road. It reflects the level of accessibility of each delegation.
Connection rate to drinking water	The proportion of housing connected to the drinking water network (SONEDE) in the delegation. It reflects the quality of life.
Number of doctors per 1000 inhabitants	The density of general doctors (medical density) per 1000 inhabitants. It reflects the level of accessibility to medical care in the delegation.
Number of beds per 1000 inhabitants	The availability of beds in hospitals per 1000 inhabitants. It reflects the capacity of public hospitals in the delegation.
Number of pharmacies per 1000 inhabitants	The density of pharmacies per 1000 inhabitants. It reflects the distribution of the medical service level in the delegation
Number of leisure centres per 1000 inhabitants	The density of turf stadiums, sports halls, youth centres, children's clubs, and complex children per 1000 inhabitants. It reflects the level of diffusion of the leisure centres in the delegation.
Diversity of leisure centres	Synthetic index calculated on the basis of the Herfindahl index to assess the level of diversity of leisure in the delegation on the basis of available information regarding the number of turf stadiums, sports halls, youth centres, children's clubs and children's complex. It takes values in the range [0, 1]; a value close to 0 (respectively 1) indicates a high (respectively low) diversity.
Category II: **Socio-demographic Environment**	
Poverty rate	This rate is defined according to the INS, as the sum of food and non-food components on the fringe of the population located in the 20th percentile in household spending.
Illiteracy rate	Part of the inhabitants do not have all tangible skills, cognitive of reading and writing
Dependency rate of the population	The part of individuals taken care of by their families. This rate is calculated as the number of people aged fewer than 15 and over 60 years compared to the total number of inhabitants of the delegation.
Number of Needy Families per 1000 habitants	The number of families taking advantage of direct assistance from the State and the allocation of the National Programme Assistance to Needy Families "PNAFN" for 1000 people in

	the delegation.
Population density per km2	The number of inhabitants per km2.
Polarization of the population's age structure	Synthetic index calculated on the basis of the Herfindahl index from the structure by age group of the population of the inhabitants of the delegation. It takes values in the range [0, 1]; a value close to 0 (respectively 1) indicates a high (respectively low) polarization or a low (respectively, lower) dispersion.
Net migration	Net migration is the difference between the number of people who entered the territory of the delegation and the number of people who came out in 2008.
Annual average growth rate of the population	Annual average increasing of the inhabitants of the delegation between 2008 and 2012
Part of educated inhabitants	The number of individuals assigns a level of secondary and higher education based on the total population of the Delegation
Average number of students per class in basic education	The ratio between the number of students and number of basic education classes.
Average number of pupils per teacher in secondary education	The ratio between the number of students and the number of secondary school teachers
Category III: Economic Environment and Employment	
Number of job offers per 1000 inhabitants	The total number of job offers registered at the employment offices of the Delegation for 1000 people in the year 2012
Number of firms per 1000 inhabitants	The number of private companies operating in the territory of the Delegation for 1000 people.
Investment's rate	The rate of job applications registered at the employment offices of the delegation has given rise to an insertion in the company during the year 2012.
Polarization sector of the labour force	Synthetic index calculated on the basis of the Herfindahl index to assess the level of diversity of the employed population by areas activity. It takes values in the range [0, 1]; a value close to 1 (respectively 0) indicates a high (respectively low) polarization of the employed population around a small number of industry
Specificity of the activity structure of the labour force	Synthetic index calculated on the basis of Krugman index to measure the difference of the structure of activities of the employed population of the delegation with the business structure of the labour force for the entire country. It takes values in the range [0, 1]; a value close to 1 (respectively 0) indicates a high (respectively low) specificity.
Index of economic concentration	Specific measure of the concentration of the structure of economic activities in the delegation. It takes values in the range [0, 1]; a value close to 1 (respectively 0) indicates a high (respectively low) businesses polarization around a limited number of activities' sectors.
Average size of the private sector's firms	The average number of employees and self-employed per company in the delegation.
Part of employment in the private sector's firms	The total number of employees based on the total active population in the Delegation
Number of job application per 1000 inhabitants	The total number of job applications registered at the employment offices of the delegation for 1000 people during 2012.

Unemployment rate	Share of unoccupied labour force in search of employment in the Delegation

The Life-Cycle of Organizations: The Characteristics of the Development Phases of the Tunisian Organizations

Salma Zone
Tunisia, amidiste@yahoo.fr

Abstract

This article discusses the life cycle of agri-food sector organizations in Tunisia. Although much research on the organization's life-cycle can be found in the literature, there is a remarkable lack of this type of research in emerging countries such as Tunisia. We begin by examining the life cycle models of organization that have been proposed in the literature. Each of these models identifies characteristics of organizations to certain stages of development. A summary model of the different phases is derived. This model includes five phases: start-up, growth, maturity, decline and revitalization. Then an organizational measurement framework developed by Lester and Parnell (2008) was introduced. This framework organizes the organizational measure criteria of each phase of the organization's life-cycle. The identification of the profiles of Tunisian organizations and the categories of the organization's life-cycle phases are determined following the use of cluster analysis (hierarchical and non-hierarchical) and analysis of variance. Analysis of the Tunisian agribusiness organizations demonstrated that organizations move from one phase to another by preserving the level of the specialized in the organization even with little embodiment of certain differentiation. The process of information and decision making change from one phase to another. These firms are also characterized by an abnormal slow change in the structuring and formalization.

Keywords: life cycle, organization, phases.

Introduction

Ontogenetic theory uses the concept of "life cycle" to better understand the profile of the evolution of the organization (Mathe 2004; Desreumaux 1998). According to the biological concept, organizations are born, try to grow by taking many forms, and eventually die. This deterministic design has long been studied in presenting the organization in the form of scenarios or phases.

The authors multiply the work to define the phases of the organization's life-cycle by enhancing the structure (Dodge and Robbins, 1992; Mintzberg 1989, Quinn and Cameron, 1983); strategy (Miller and Friesen, 1984; Chandler, 1992); performance (Lester, Parnell and Carrahar, 2003); any problems (Churchill and Lewis, 1983; Greiner, 1977). These authors are keen in specifying the life cycle of the organization and describing each phase of the life-cycle.

However, the examination of the literature shows that there are convergences of the different models studied and absence of the specification of the life cycle model of the Tunisian organizations. We will be ambitious and to specify the life-cycle of the Tunisian organization in the Tunisian food industry and to present the main features.

The Theoretical Framework

The organization is defines as an open system composed of interacting elements. Its development involves the transformation of these elements (Mintzberg, 1982).

According to the evolutionists, the organization evolves by learning (Tanguy, 1999; Coriat and Weinstein, 1999). According to the biological concept, organization concerned with sustainability and change tends to find balance between continuity and innovation. It seeks to improve its skills and to adapt to the environment. Indeed, the organization can ensure its survival as through responses to the environment (Pfeffer and Salancik 1978), training routines (Nelson and Winter, 1982), changes in configurations (Chandler , 1992) and inertial factors (Miller, 1992). These elements define the profile of the evolution of an organization.

Often apprehended by the joint influence between environment and organization, the evolution is explained by its profile, its duration and its mechanisms (Mathé 2004). A study of the pace of evolution proves important before treating the organization's life-cycle.

The organization's lifecycle presents stages of life interpreted as incremental changes cycles where organizations are transformed periodically (Hafsi and Demers, 1997).

The Rhythm of the Organization's Development

The evolution aims the managerial adjustments in order to maintain growth. It is determined by the economic environment (Hannen & Freeman, 1977), proactive leadership roles (Desreumaux, 1998), the organisation-environment influence, inertia and routines (Feldman, 2000).

Thus, organizations depend on their environment for the resources they use. The population ecology theory apprehends organizations from the environmental point of view. Thus, organizations evolve following environment adaptation. The theory of resource dependence sides with the organization whose managers can anticipate the sources of the environment.

After determining the evolution of the organization levers, the period seems to be the ground to be explored. Add to that, the evolution obeys periods of evolution and revolution, or periods of stability and change. Regardless of rhythm, a plausible hypothesis tends to describe the life-cycle of the organization through phases.

Table 1: The various rhythms of the organizational development

Types of change	Characteristics
Incremental	The change can bel: ➲ indeterminate: Thus the organization goes through a natural evolution period and a period of revolution (Greiner 1977). According to this mechanical approach, the organization examines the difficulties and tries to solve the crises. ➲ Gradual: it is thus sequential, indefinite therefore progressive. It is provided by: ▪ The paradigms that develop gradually and not abruptly. All of these beliefs and convictions help the organization to renew itself (Johnson and Scholes, 2000). ▪ The chaos in which the organization seeks to find a balance with order. The organization develops following the mobilization of resources at one level, and looking for change at a second one (Laszlo and Laugel, 1998).
Dynamic	The dynamic evolution occurs following the transmission of the myths (March 1999). It is characterized by periods of continuity and those of

	rupture. These myths play a stabilizing role and a dynamic one.
Continuous	The continuous evolution is provided by the research continuity and change. It is based on: ➲ Sustainability: according to the theological approach, the principle of evolution is the will and according to the evolutionary approach, the source of change is the confrontation between continuity and change (Desreumaux, 1998; Mignon, 2002). ➲ The vision: the evolution of the organization is continuous but conditioned by self-discipline, visionary ability and dynamic balance between continuity and change (Collins and Porras, 1993).

Thus, the evolution of the organization through two periods: a period of continuity or balance, and a period of revolution or change. According to the punctuated equilibrium, evolution is understood by long periods of permanence where structures and strategies do not change but evolve incrementally, and periods of changes and fluctuations. Thus the organization inexorably goes through periods of transition schematically by a life-cycle.

The Organization's Life-Cycle

The life-cycle of the organizations (CVO) " is defined by the internal characteristics of the organizations and the external context in which they operate" (Silvola, 2008: 29). By adopting the biological concept, it “is more of a collective interpretation of the organization's environment based on an assessment by top management. Most firms do not pas inexorably from one stage of development to another in the traditional biological sense "(Lester, Parnell and Carraher 2003: 340).
